

FEATURES

IQ demodulator with integrated fractional-N PLL

LO frequency range: 700 MHz to 1050 MHz

For the following specifications (LPEN = 0)/(LPEN = 1):

Input P1dB: 12.8 dBm/11.7 dBm

Input IP3: 26.7 dBm/24.0 dBm

Noise figure (DSB): 13.1 dB/12.4 dB

Voltage conversion gain: 1.0 dB/4.3 dB

Quadrature demodulation accuracy

Phase accuracy: <0.5°

Amplitude accuracy: <0.1 dB

Baseband demodulation: 170 MHz/135 MHz, 3 dB bandwidth

SPI serial interface for PLL programming

40-lead, 6 mm × 6 mm LFCSP

APPLICATIONS

QAM/QPSK RF/IF demodulators

Cellular W-CDMA/CDMA/CDMA2000

Microwave point-to-(multi)point radios

Broadband wireless and WiMAX

GENERAL DESCRIPTION

The **ADRF6807** is a high dynamic range IQ demodulator with integrated phase-locked loop (PLL) and voltage controlled oscillator (VCO). The fractional-N PLL/synthesizer generates a frequency in the range of 2.8 GHz to 4.2 GHz. A programmable quadrature divider (divide ratio = 4) divides the output frequency of the VCO down to the required local oscillator (LO) frequency to drive the mixers in quadrature. Additionally, an output divider (divide ratio = 4 to 8) generates a divided-down VCO signal for external use.

The PLL reference input is supported from 9 MHz to 160 MHz. The phase detector output controls a charge pump whose output is integrated in an off-chip loop filter. The loop filter output is then applied to an integrated VCO.

The IQ demodulator mixes the differential RF input with the complex LO derived from the quadrature divider. The differential I and Q output paths have excellent quadrature accuracy and can handle baseband signaling or complex IF up to 120 MHz.

A reduced power mode of operation is also provided by programming the serial interface registers to reduce current consumption, with slightly degraded input linearity and output current drive.

The **ADRF6807** is fabricated using an advanced silicon-germanium BiCMOS process. It is available in a 40-lead, exposed paddle, RoHS-compliant, 6 mm × 6 mm LFCSP package. Performance is specified over the -40°C to +85°C temperature range.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
Supply Voltage, VCCBB and VCCRF (V_{S1})	-0.5 V to +5.5 V
Supply Voltage, VCC1, VCC2, and VCCLO (V_{S2})	-0.5 V to +3.6 V
Digital I/O, CLK, DATA, and LE	-0.3 V to +3.6 V
RFIP and RFIN (Each Pin AC-Coupled)	13 dBm
θ_{JA} (Exposed Paddle Soldered Down)	30°C/W
Maximum Junction Temperature	150°C
Operating Temperature Range	-40°C to +85°C
Storage Temperature Range	-65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NOTES
 1. THE EXPOSED PADDLE SHOULD BE SOLDERED TO A LOW IMPEDANCE GROUND PLANE.

Figure 3. Pin Configuration

09993-003

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
1, 2	VCC1	The 3.3 V Power Supply for VCO and PLL.
3	CPOUT	Charge Pump Output Pin. Connect this pin to VTUNE through the loop filter.
4, 7, 11, 15, 16, 20, 21, 24, 27, 30, 31, 35	GND	Ground. Connect these pins to a low impedance ground plane.
5	RSET	Charge Pump Current. The nominal charge pump current can be set to 250 μA, 500 μA, 750 μA, or 1 mA using DB10 and DB11 of Register 4 and by setting DB18 to 0 (internal reference current). In this mode, no external RSET is required. If DB18 is set to 1, the four nominal charge pump currents (INOMINAL) can be externally tweaked according to the following equation where the resulting value is in units of ohms. $R_{SET} = \left[\frac{217.4 \times I_{CP}}{I_{NOMINAL}} \right] - 37.8$

Pin No.	Mnemonic	Description
6	REFIN	Reference Input. Nominal input level is 1 V p-p. Input range is 9 MHz to 160 MHz.
8	MUXOUT	Multiplexer Output. This output can be programmed to provide the reference output signal or the lock detect signal. The output is selected by programming the appropriate register.
9	DECL2	Connect a 0.1 μ F capacitor between this pin and ground.
10	VCC2	3.3 V Power Supply for 2.5 V LDO.
12	DATA	Serial Data Input. The serial data is loaded MSB first with the three LSBs being the control bits.
13	CLK	Serial Clock Input. This serial clock is used to clock in the serial data to the registers. The data is latched into the 24-bit shift register on the CLK rising edge. Maximum clock frequency is 20 MHz.
14	LE	Load Enable. When the LE input pin goes high, the data stored in the shift registers is loaded into one of the six registers, the relevant latch being selected by the first three control bits of the 24-bit word.
17, 34	VCCLO	3.3 V Power Supply for LO Path Blocks.
18, 19	QBBP, QBBN	Demodulator Q-Channel Differential Baseband Outputs (Differential Output Impedance of 28 Ω).
22	VCCBB	5 V Power Supply for Demodulator Blocks.
23	VOCM	Baseband Common-Mode Reference Input; 1.65 V Nominal. It sets the dc common-mode level of the IBx and QBBx outputs.
25, 26	RFIP, RFIN	Differential 100 Ω , Internally Biased RF Inputs. These pins must be ac-coupled.
28	VCCRF	5 V Power Supply for Demodulator Blocks.
29	DECL3	Connect a 2.2 μ F capacitor between this pin and ground.
32, 33	IBBN, IBBP	Demodulator I-Channel Differential Baseband Outputs (Differential Output Impedance of 28 Ω).
36	LOSEL	LO Select. Connect this pin to ground for the simplest operation and to completely control the LO path and input/output direction from the register programming of the SPI. For additional control without register reprogramming, this input pin can determine whether the LOP and LON pins operate as inputs or outputs. LOP and LON become inputs if the LOSEL pin is set low, the LDRV bit of Register 5 is set low, and the LXL bit of Register 5 is set high. The externally applied LO drive must be at M \times LO frequency (where M corresponds to the main LO divider setting). LON and LOP become outputs when LOSEL is high or if the LDRV bit of Register 5 (DB3) is set high and the LXL bit of Register 5 (DB4) is set to low. The output frequency is controlled by the LO output divider bits in Register 7. This pin should not be left floating.
37, 38	LON, LOP	Local Oscillator Input/Output (Differential Output Impedance of 28 Ω). When these pins are used as output pins, a differential frequency divided version of the internal VCO is available on these pins. When the internal LO generation is disabled, an external M \times LO frequency signal can be applied to these pins, where M corresponds to the main divider setting.
39	VTUNE	VCO Control Voltage Input. This pin is driven by the output of the loop filter. The nominal input voltage range on this pin is 1.0 V to 2.8 V.
40	DECL1	Connect a 10 μ F capacitor between this pin and ground as close to the device as possible because this pin serves as the VCO supply and loop filter reference.
	EP	Exposed Paddle. The exposed paddle should be soldered to a low impedance ground plane.

TYPICAL PERFORMANCE CHARACTERISTICS

$V_{S1} = 5\text{ V}$, $V_{S2} = 3.3\text{ V}$, $T_A = 25^\circ\text{C}$, RF input balun loss is de-embedded, unless otherwise noted. LO = 700 MHz to 1050 MHz; Mini-Circuits ADTL2-18 balun on RF inputs.

CIRCUIT DESCRIPTION

The [ADRF6807](#) integrates a high performance IQ demodulator with a state-of-the-art fractional-N PLL. The PLL also integrates a low noise VCO. The SPI port allows the user to control the fractional-N PLL functions, the demodulator LO divider functions, and optimization functions, as well as allowing for an externally applied LO.

The [ADRF6807](#) uses a high performance mixer core that results in an exceptional input IP3 and input P1dB, with a very low output noise floor for excellent dynamic range.

LO QUADRATURE DRIVE

A signal at 2× the desired mixer LO frequency is delivered to a divide-by-2 quadrature phase splitter followed by limiting amplifiers, which then drive the I and Q mixers, respectively.

V-TO-I CONVERTER

The differential RF input signal is applied to a V-to-I converter that converts the differential input voltage to output currents. The V-to-I converter provides a differential 100 Ω input impedance. The V-to-I bias current can be reduced by putting the device in low power mode (setting LPEN = 1 by setting Register 5, DB5 = 1). Generally with LPEN = 1, input IP3 and input P1dB degrade, but the noise figure is slightly better. Overall, the dynamic range is reduced by setting LPEN = 1.

MIXERS

The [ADRF6807](#) has two double-balanced mixers: one for the in-phase channel (I channel) and one for the quadrature channel (Q channel). These mixers are based on the Gilbert cell design of four cross-connected transistors. The output currents from the two mixers are summed together in the resistive loads that then feed into the subsequent emitter follower buffers. When the part is put into its low power mode (LPEN = 1), the mixer core load resistors are increased, which does increase the gain by roughly 3 dB; however, as previously stated in the V-to-I Converter section, the overall dynamic range does decrease slightly.

EMITTER FOLLOWER BUFFERS

The output emitter followers drive the differential I and Q signals off chip. The output impedance is set by on-chip 14 Ω series resistors that yield a 28 Ω differential output impedance for each baseband port. The fixed output impedance forms a voltage divider with the load impedance that reduces the effective gain. For example, a 500 Ω differential load has ~0.5 dB lower effective gain than a high (10 kΩ) differential load impedance.

The common-mode dc output levels of the emitter follower outputs are set by the voltage applied to the VOCM pin. The VOCM pin must be driven with a voltage (typically 1.65 V) for the emitter follower buffers to function. If the VOCM pin is left open, the emitter follower outputs do not bias up properly.

BIAS CIRCUITRY

There are several band gap reference circuits and two low dropout regulators (LDOs) in the [ADRF6807](#) that generate the reference currents and voltages used by different sections. One of the LDOs is the 2.5V_LDO, which is always active and provides the 2.5 V supply rail used by the internal digital logic blocks. The 2.5V_LDO output is connected to the DECL2 pin (Pin 9) for the user to provide external decoupling. The other LDO is the VCO_LDO, which acts as the positive supply rail for the internal VCO. The VCO_LDO output is connected to the DECL1 pin (Pin 40) for the user to provide external decoupling. The VCO_LDO can be powered down by setting Register 6, DB18 = 0, which allows the user to save power when not using the VCO. Additionally, the bias current for the mixer V-to-I stage, which drives the mixer core, can be reduced by putting the device in low power mode (setting LPEN = 1 by setting Register 5, DB5 = 1).

REGISTER STRUCTURE

The [ADRF6807](#) provides access to its many programmable features through a 3-wire SPI control interface that is used to program the seven internal registers. The minimum delay and hold times are shown in the timing diagram (see Figure 2). The SPI provides digital control of the internal PLL/VCO as well as several other features related to the demodulator core, on-chip referencing, and available system monitoring functions. The MUXOUT pin provides a convenient, single-pin monitor output signal that can be used to deliver a PLL lock-detect signal or an internal voltage proportional to the local junction temperature.

Note that internal calibration for the PLL must run when the [ADRF6807](#) is initialized at a given frequency. This calibration is run automatically whenever Register 0, Register 1, or Register 2 is programmed. Because the other registers affect PLL performance, Register 0, Register 1, and Register 2 must always be programmed last. For ease of use, starting the initial programming with Register 7 and then programming the registers in descending order ending with Register 0 is recommended. Once the PLL and other settings are programmed, the user can change the PLL frequency simply by programming Register 0, Register 1, or Register 2 as necessary.

Figure 33. Integer Divide Control Register (R0)

Register 0—Integer Divide Control

With R0[2:0] set to 000, the on-chip integer divide control register is programmed as shown in Figure 33. The internal VCO frequency (f_{VCO}) equation is

$$f_{VCO} = f_{PPD} \times (INT + (FRAC/MOD)) \times 2 \tag{1}$$

where:

- f_{VCO} is the output frequency of the internal VCO.
- INT is the preset integer divide ratio value (21 to 123 for integer mode, 24 to 119 for fractional mode).
- $FRAC$ is the preset fractional divider ratio value (0 to $MOD - 1$).
- MOD is the preset fractional modulus (1 to 2047).

The integer divide ratio sets the INT value in Equation 1. The INT, FRAC, and MOD values make it possible to generate output frequencies that are spaced by fractions of the PFD frequency.

Note that the demodulator LO frequency is given by $f_{LO} = f_{VCO}/M$, where M is the programmed LO main divider (see Table 5).

Divide Mode

Divide mode determines whether fractional mode or integer mode is used. In integer mode, the VCO output frequency, f_{VCO} , is calculated by

$$f_{VCO} = f_{PPD} \times (INT) \times 2 \tag{2}$$

Register 1—Modulus Divide Control

With R1[2:0] set to 001, the on-chip modulus divide control register is programmed as shown in Figure 34. The MOD value is the preset fractional modulus ranging from 1 to 2047.

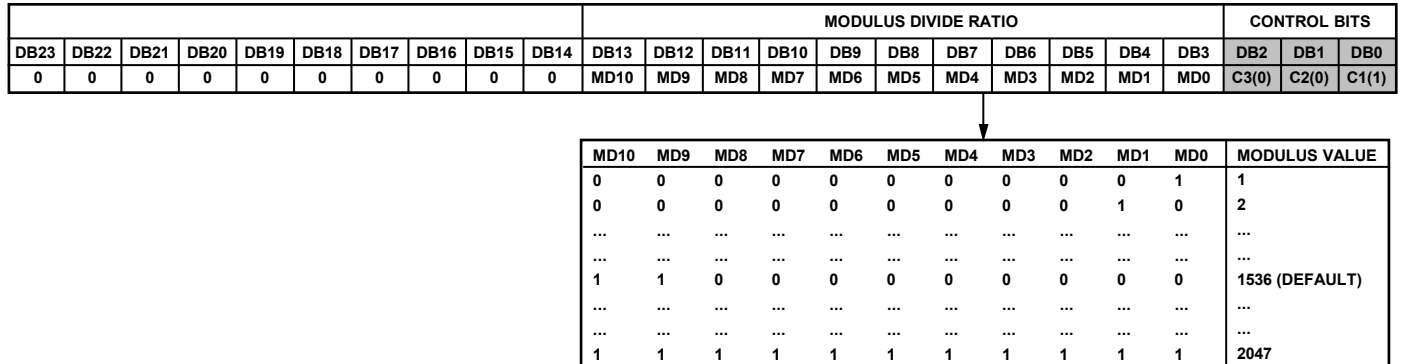

Figure 34. Modulus Divide Control Register (R1)

Register 2—Fractional Divide Control

With R2[2:0] set to 010, the on-chip fractional divide control register is programmed as shown in Figure 35. The FRAC value is the preset fractional modulus ranging from 0 to MOD – 1.

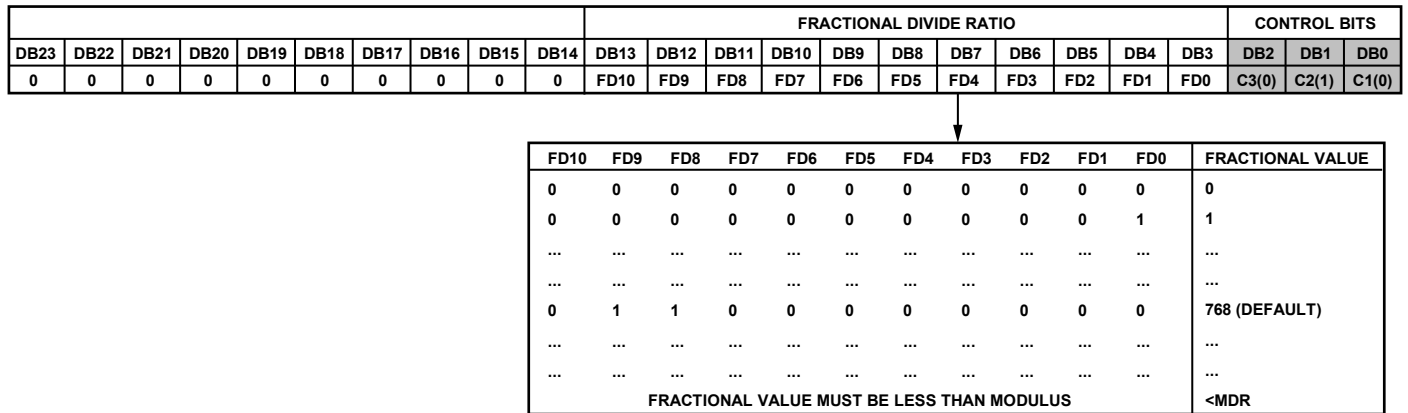

Figure 35. Fractional Divide Control Register (R2)

Register 3—Sigma Delta (Σ - Δ) Modulator Dither Control

With R3[2:0] set to 011, the on-chip Σ - Δ modulator dither control register is programmed as shown in Figure 36. The dither restart value can be programmed from 0 to 217, though a value of 1 is typically recommended.

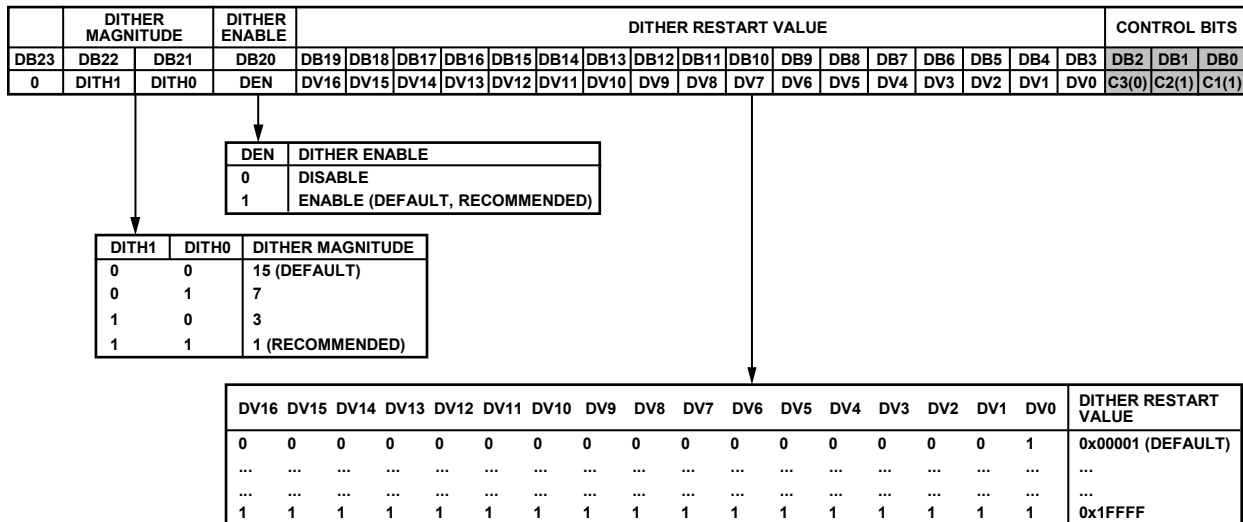

Figure 36. Σ - Δ Modulator Dither Control Register (R3)

Register 4—Charge Pump, PFD, and Reference Path Control

With R4[2:0] set to 100, the on-chip charge pump, PFD, and reference path control register is programmed as shown in Figure 37.

The charge pump current is controlled by the base charge pump current ($I_{CP, BASE}$), and the value of the charge pump current multiplier ($I_{CP, MULT}$).

The base charge pump current can be set using an internal or external resistor (according to DB18 of Register 4). When using an external resistor, the value of $I_{CP, BASE}$ can be varied according to

$$R_{SET} [\Omega] = \left[\frac{217.4 \times I_{CP, BASE}}{250} \right] - 37.8$$

The actual charge pump current can be programmed to be a multiple (1, 2, 3, or 4) of the charge pump base current. The multiplying value ($I_{CP, MULT}$) is equal to 1 plus the value of the DB11 and DB10 bits in Register 4.

The PFD phase offset multiplier ($\theta_{PFD, OFS}$), which is set by Bit DB16 to Bit DB12 of Register 4, causes the PLL to lock with a nominally fixed phase offset between the PFD reference signal

and the divided-down VCO signal. This phase offset is used to linearize the PFD-CP transfer function and can improve fractional spurs. The magnitude of the phase offset is determined by

$$|\Delta\Phi| [\text{deg}] = 22.5 \frac{\theta_{PFD, OFS}}{I_{CP, MULT}}$$

Finally, the phase offset can be either positive or negative, depending on the value of the DB17 bit in Register 4.

The reference frequency applied to the PFD can be manipulated using the internal reference path source. The external reference frequency applied can be internally scaled in frequency by 2×, 1×, 0.5×, or 0.25×. This allows a broader range of reference frequency selections while keeping the reference frequency applied to the PFD within an acceptable range.

The [ADRF6807](#) also provides a MUXOUT pin that can be programmed to output a selection of several internal signals. The default mode provides a lock-detect output that allows users to verify when the PLL has locked to the target frequency. In addition, several other internal signals can be routed to the MUXOUT pin as shown in Figure 37.

Figure 37. Charge Pump, PFD, and Reference Path Control Register (R4)

Register 5—LO Path and Demodulator Control

With R5[DB5] = 1, the ADRF6807 is in a lower power operating mode. The device is still fully functional in this lower power mode, but the mixer performance is shifted (see the Typical Performance Characteristics section for details on performance differences). Setting R5[DB5] = 0 causes the ADRF6807 mixer stage to run at a higher current, thereby achieving a higher IIP3.

Register 5 also controls whether the LOIP and LOIN pins act as an input or output and whether the output driver is enabled as detailed in Figure 38.

Figure 38. LO Path and Demodulator Control Register (R5)

09P93-036

Register 6—VCO Control and Enables

With R6[2:0] set to 110, the VCO control and enables register is programmed as shown in Figure 39.

VCO band selection is normally selected based on an internal BANDCAL calibration; however, the VCO band can be selected directly using Register 6. The VCO BS SRC determines whether the BANDCAL calibration determines the optimum VCO tuning band or if the external SPI interface is used to select the VCO tuning band based on the value of the VCO band select.

The VCO amplitude can be controlled through Register 6. The VCO amplitude setting can be controlled between 0 and 31 decimal, with a default value of 24.

The internal VCO can be disabled using Register 6. The internal VCO LDO can be disabled if an external clean 3.0 V supply is available.

The internal charge pump can be disabled through Register 6. Normally, the charge pump is enabled.

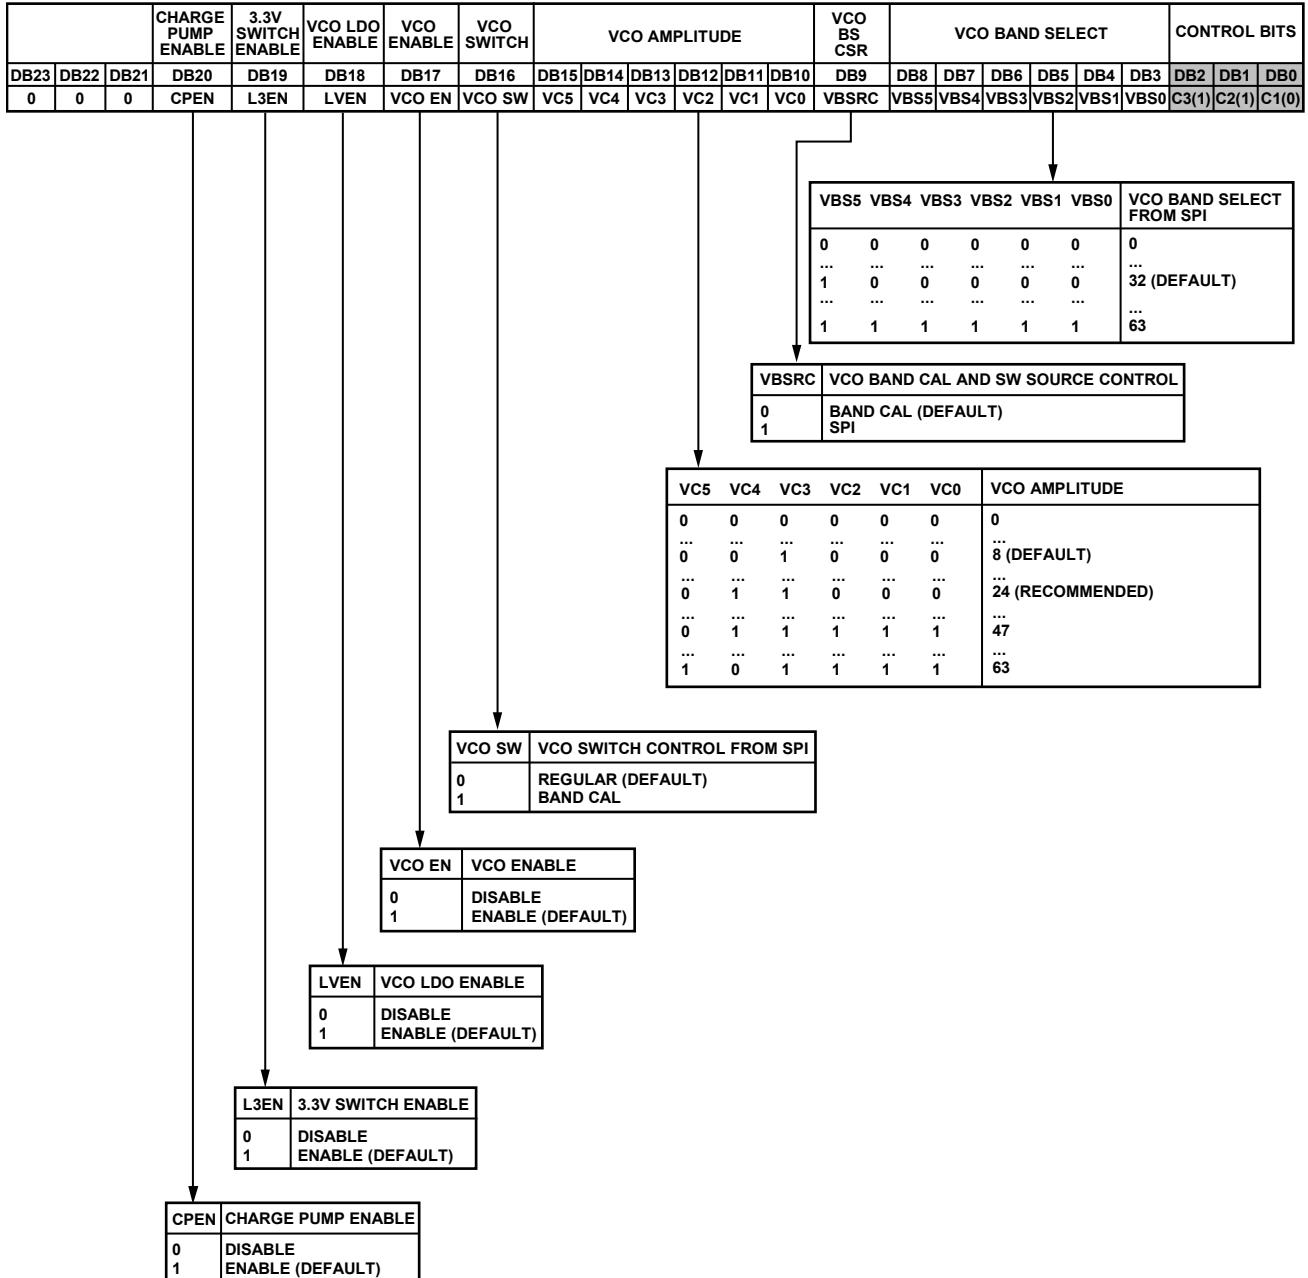

Figure 39. VCO Control and Enables (R6)

Register 7—LO Divider Control

Register 7 controls the LO path main divider settings as well as the LO output path divider setting. Table 5 indicates how to program this register to achieve the specified divider mode.

Figure 40. LO Divider Control Register (R7)

09963-038

LO DIVIDER PROGRAMMING

Table 5. Main Divider (Only Divide Ratios and Combinations Specified Are Guaranteed)

f _{LO} (MHz)	LO Divider Ratio	f _{VCO} (MHz)	Divider Cascade			Register 7, DB[9:6]
			Divide-by-2 to Divide-by-5	Divide-by-2, Divide-by-4, or Divide-by-8	Quadrature Divide-by-2	
700 to 1050	4	2800 to 4200	2	Not used	2	00 00

Table 6. Output Divider

f _{LO} Output (MHz)	Output Divider Ratio	f _{VCO} (MHz)	Register 7, DB[5:4]
350 to 525	8	2800 to 4200	11
466.67 to 700	6	2800 to 4200	10
700 to 1050	4	2800 to 4200	01

PROGRAMMING EXAMPLE

For example, internal LO frequency = 700 MHz. This can be accomplished with the VCO/PLL frequency at 2800 MHz and an LO divide ratio of 4. The choice of output divider ratio of 8 gives an output frequency of 350 MHz. To achieve this combination, a binary code of 00 00 11 should be programmed into DB[9:4] of Register 7.

APPLICATIONS INFORMATION

BASIC CONNECTIONS

The basic circuit connections for a typical ADRF6807 application are shown in Figure 41.

SUPPLY CONNECTIONS

The ADRF6807 has several supply connections and on-board regulated reference voltages that should be bypassed to ground using low inductance bypass capacitors located in close proximity to the supply and reference pins of the ADRF6807. Specifically, Pin 1, Pin 2, Pin 9, Pin 10, Pin 17, Pin 22, Pin 23, Pin 28, Pin 29, Pin 34, and Pin 40 should be bypassed to ground using individual bypass capacitors. Pin 40 is the decoupling pin for the on-board VCO LDO, and for best phase noise performance, several bypass capacitors ranging from 100 pF to 10 μ F may help to improve phase noise performance. For additional details on bypassing the supply nodes, see the evaluation board schematic in Figure 43.

SYNTHESIZER CONNECTIONS

The ADRF6807 includes an on-board VCO and PLL for LO synthesis. An external reference must be applied for the PLL to operate. A 1 V p-p nominal external reference must be applied to Pin 6 through an ac coupling capacitor. The reference is compared to an internally divided version of the VCO output frequency to create a charge pump error current to control and lock the VCO. The charge pump output current is filtered and converted to a control voltage through the external loop filter that is then applied to the VTUNE pin (Pin 39). ADIsimPLL™ can be a helpful tool when designing the external charge pump loop filter. The typical K_v of the VCO, the charge pump output current magnitude, and PFD frequency should all be considered when designing the loop filter. The charge pump current magnitude can be set internally or with an external RSET resistor connected to Pin 5 and ground, along with the internal digital settings applied to the PLL (see the Register 4—Charge Pump, PFD, and Reference Path Control section for more details).

Figure 41. Basic Connections

09993-039

I/Q OUTPUT CONNECTIONS

The [ADRF6807](#) has I and Q baseband outputs. Each output stage consists of emitter follower output transistors with a low differential impedance of 28 Ω and can source up to 12 mA p-p differentially. A Mini-Circuits TCM9-1+ balun is used to transform a single-ended 50 Ω load impedance into a nominal 450 Ω differential impedance.

RF INPUT CONNECTIONS

The [ADRF6807](#) uses a Mini-Circuits ADTL2-18+ balun with a 2:1 impedance ratio to transform a single-ended 50 Ω impedance into a differential 100 Ω impedance. Coupling capacitors whose impedance is small compared to 100 Ω at the frequency of operation are used to isolate the dc bias points of the RF input stage.

CHARGE PUMP/VTUNE CONNECTIONS

The [ADRF6807](#) uses a loop filter to create the VTUNE voltage for the internal VCO. The loop filter in its simplest form is an integrating capacitor. It converts the current mode error signal coming out of the CPOUT pin into a voltage to control the VCO via the VTUNE voltage. The stock filter on the evaluation board has a bandwidth of 67 kHz. The loop filter contains five components, three capacitors, and two resistors. Changing the values of these components changes the bandwidth of the loop filter.

LO SELECT INTERFACE

The [ADRF6807](#) has the option of either monitoring a scaled version of the internally generated LO (LOSEL pin driven high at 3.3 V) or providing an external LO source (LOSEL pin driven low to ground, the LDRV bit in Register 5 set low, and the LXL bit in Register 5 set high). See the Pin Configuration and Function Descriptions section for full operation details.

EXTERNAL LO INTERFACE

The [ADRF6807](#) provides the option to use an external signal source for the LO into the IQ demodulating mixer core. It is important to note that the applied LO signal is divided down by a divider (programmable to between 4 and 80) prior to the actual IQ demodulating mixer core. The divider is determined by the register settings in the LO path and mixer control register (see the Register 5—LO Path and Demodulator Control section). The LO input pins (Pin 37 and Pin 38) present a broadband differential 50 Ω input impedance. The LOP and LON input pins must be ac-coupled. This is achieved on the evaluation board via a Mini-Circuits TC1-1-13+ balun with a 1:1 impedance ratio. When not in use, the LOP and LON pins can be left unconnected.

SETTING THE FREQUENCY OF THE PLL

The frequency of the VCO/PLL, once locked, is governed by the values programmed into the PLL registers, as follows:

$$f_{PLL} = f_{PPD} \times 2 \times (INT + FRAC/MOD)$$

where:

f_{PLL} is the frequency at the VCO when the loop is locked.

f_{PPD} is the frequency at the input of the phase frequency detector.

INT is the integer divide ratio programmed into Register 0.

$FRAC$ is the fractional value programmed into Register 2.

MOD is the modulus divide ratio programmed into Register 1.

The practical lower limit of the reference input frequency is determined by the combination of the desired f_{PLL} and the maximum programmable integer divide ratio of 119 and reference input frequency multiplier of 2. For a maximum f_{PLL} of 4200 MHz,

$$f_{REF} > \sim f_{PLL} / (f_{PPD} \times 2 \times 2), \text{ or } 8.8 \text{ MHz}$$

A lock detect signal is available as one of the selectable outputs through the MUXOUT pin, with logic high signifying that the loop is locked.

REGISTER PROGRAMMING

Because Register 6 controls the powering of the VCO and charge pump, it must be programmed once before programming the PLL frequency (Register 0, Register 1, and Register 2).

The registers should be programmed starting with the highest register (Register 7) first and then sequentially down to Register 0 last. When Register 0, Register 1, or Register 2 is programmed, an internal VCO calibration is initiated that must execute when the other registers are set. Therefore, the order must be Register 7, Register 6, Register 5, Register 4, Register 3, Register 2, Register 1, and then Register 0. Whenever Register 0, Register 1, or Register 2 is written to, it initializes the VCO calibration (even if the value in these registers does not change). After the device has been powered up and the registers configured for the desired mode of operation, only Register 0, Register 1, or Register 2 must be programmed to change the LO frequency.

If none of the register values are changing from their defaults, there is no need to program them.

EVM MEASUREMENTS

EVM is a measure used to quantify the performance of a digital radio transmitter or receiver. A signal received by a receiver has all constellation points at their ideal locations; however, various imperfections in the implementation (such as magnitude imbalance, noise floor, and phase imbalance) cause the actual constellation points to deviate from their ideal locations.

In general, a demodulator exhibits three distinct EVM limitations vs. received input signal power. As signal power increases, the distortion components increase. At large signal levels, where the distortion components due to the harmonic nonlinearities in the device are falling in-band, EVM degrades as signal levels increase. At medium signal levels, where the demodulator behaves in a linear manner and the signal is well above any notable noise contributions, the EVM has a tendency to reach an optimal level determined dominantly by either quadrature accuracy and I/Q gain match of the demodulator or the precision of the test equipment. As signal levels decrease, such that the noise is a major contribution, the EVM performance vs. the signal level exhibits a decibel-for-decibel degradation with decreasing signal level. At lower signal levels, where noise proves to be the dominant limitation, the decibel EVM proves to be directly proportional to the SNR.

The basic test setup for testing the EVM of the [ADRF6807](#) consisted of an Agilent E4438C, which was used as a signal source. The 900 MHz modulated signal was driven single ended into the RFIN SMA connector of the [ADRF6807](#) evaluation board. The IQ baseband outputs were taken differentially into a pair of [AD8130](#) difference amplifiers to convert the differential signals to single ended. The output impedance that the [ADRF6807](#) drove was set to 450 Ω differential. The single-ended I and Q signals were then sampled by an Agilent DSO7104B oscilloscope. The Agilent 89400 VSA software was used to calculate the EVM of the signal. The signal source that was used for the reference input was a Wenzel 100 MHz quartz oscillator set at an amplitude of 1 V p-p. The reference path was set to a divide-by-four, thus making the PFD frequency 25 MHz.

Figure 42 shows the excellent EVM of the [ADRF6807](#) being better than -40 dB over an RF input range of about 40 dB for a 4 QAM modulated signal, at a 5 MHz symbol rate and at a 0 Hz IF. The roll-off, or alpha, of the pulse shaping filter was set to 0.35. The reported RF input power is the power integrated across the bandwidth of

$$BW = (1 + \alpha) \times (\text{Symbol Rate})$$

EVM was tested for both power modes: low power mode disabled (LPEN = 0) and low power mode enabled (LPEN = 1). When the low power mode is enabled, the EVM is better at lower RF input signal levels due to less noise while running in the low power mode.

Figure 42. EVM Measurements at 900 MHz 4 QAM, Symbol Rate = 5 MHz, Baseband Frequency = 0 Hz IF

EVALUATION BOARD LAYOUT AND THERMAL GROUNDING

An evaluation board is available for testing the [ADRF6807](#). The evaluation board schematic is shown in Figure 43.

Table 7 provides the component values and suggestions for modifying the component values for the various modes of operation.

09993-042

Figure 43. Evaluation Board Schematic

09993-144

Figure 44. Evaluation Board USB Section Schematic

The package for the [ADRF6807](#) features an exposed paddle on the underside that should be well soldered to an exposed opening in the solder mask on the evaluation board. Figure 45 illustrates the dimensions used in the layout of the [ADRF6807](#) footprint on the [ADRF6807](#) evaluation board (1 mil = 0.0254 mm).

Note the use of nine via holes on the exposed paddle. These ground vias should be connected to all other ground layers on the evaluation board to maximize heat dissipation from the device package. Under these conditions, the thermal impedance of the [ADRF6807](#) was measured to be approximately 30°C/W in still air.

ADRF6807 SOFTWARE

The [ADRF6807](#) evaluation board can be controlled from PCs using a USB adapter board, which is also available from Analog Devices, Inc. The USB adapter evaluation documentation and ordering information can be found on the [EVAL-ADF4XXXZ-USB](#) product page. The basic user interfaces are shown in Figure 48 and Figure 49.

The software allows the user to configure the [ADRF6807](#) for various modes of operation. The internal synthesizer is controlled by clicking any of the numeric values listed in **RF Section**.

Attempting to program **Ref Input Frequency**, **PFD Frequency**, **VCO Frequency (2×LO)**, **LO Frequency**, or other values in **RF Section** launches the **Synth Form** window shown in Figure 49. Using **Synth Form**, the user can specify values for **Local Oscillator Frequency (MHz)** and **External Reference Frequency (MHz)**. The user can also enable the LO output buffer and divider options from this menu. After setting the desired values, it is important to click **Upload all registers** for the new setting to take effect.

Figure 48. Evaluation Board Software Main Window

00993-148

The Synth Form window displays the following configuration parameters and controls:

- Register Status:** A table showing the status of registers 0 through 7.
- External Reference Frequency (MHz):** Set to 26.
- Input Reference Path Mux:** Options include x2, x1 (selected), x0.5, and x0.25.
- Output Mux Source:** Options include Lock Detect (selected), VPAT, 1x Ref In, 0.5x Ref In, 2x Ref In, Tristate, and 0.25x Ref In.
- PLL Parameters:** PFD Freq (MHz) is 26, VCO Frequency (MHz) is 3600, and the Divider is 69.23.
- LO Section:** Includes an Int LO block, an LO Source block, and a Divide by 2 block.
- Frequency Dividers:** A 'div by 4' block and a 'Divide by 2' block are shown in the signal path.
- Local Oscillator Frequency (MHz):** Set to 900.000.
- Channel Step Size (kHz):** Set to 12.5.
- Step Size Multiplier:** Set to 1.
- Channel Control:** Buttons for Live Inc Channel Step, Inc Channel Step, Live Dec Channel Step, and Dec Channel Step.
- Buttons:** 'Upload all registers' (yellow) and 'Exit' (blue).

Figure 49. Evaluation Board Software Synth Form Window

CHARACTERIZATION SETUPS

Figure 50 to Figure 52 show the general characterization bench setups used extensively for the [ADRF6807](#). The setup shown in Figure 50 was used to perform the bulk of the testing. An automated Agilent VEE program was used to control the equipment over the IEEE bus. This setup was used to measure gain, input P1dB, output P1dB, input IP2, input IP3, IQ gain mismatch, IQ quadrature accuracy, and supply current. The evaluation board was used to perform the characterization with a Mini-Circuits TCM9-1+ balun on each of the I and Q outputs. When using the TCM9-1+ balun below 5 MHz (the specified 1 dB low frequency corner of the balun), distortion performance degrades; however, this is not the [ADRF6807](#) degrading, merely the low frequency corner of the balun introducing distortion effects. Through this balun, the 9-to-1 impedance transformation effectively presented a 450 Ω differential load at each of the I and Q channels. The use of the

broadband Mini-Circuits ADTL2-18+ balun on the input provided a differential balanced RF input. The losses of both the input and output baluns were de-embedded from all measurements.

To perform phase noise and reference spur measurements, the setup shown in Figure 52 was used. Phase noise was measured at the baseband output (I or Q) at a baseband carrier frequency of 50 MHz. The baseband carrier of 50 MHz was chosen to allow phase noise measurements to be taken at frequencies of up to 20 MHz offset from the carrier. The noise figure was measured using the setup shown in Figure 51 at a baseband frequency of 10 MHz.
