

12A, 600V N-Channel IGBT with Anti-Parallel Ultrafast Diode

April 1995

Features

- 12A, 600V
- Latch Free Operation
- Typical Fall Time <500ns
- Low Conduction Loss
- With Anti-Parallel Diode
- $t_{RR} < 60ns$

Description

The IGBT is a MOS gated high voltage switching device combining the best features of MOSFETs and bipolar transistors. The device has the high input impedance of a MOSFET and the low on-state conduction loss of a bipolar transistor. The much lower on-state voltage drop varies only moderately between +25°C and +150°C. The diode used in parallel with the IGBT is an ultrafast ($t_{RR} < 60ns$) with soft recovery characteristic.

The IGBTs are ideal for many high voltage switching applications operating at frequencies where low conduction losses are essential, such as: AC and DC motor controls, power supplies and drivers for solenoids, relays and contactors.

NOTE:

- Turn-off Energy Loss (W_{OFF}) is defined as the integral of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero ($I_{CE} = 0\text{A}$). The HGTG12N60D1D was tested per JEDEC standard No. 24-1 Method for Measurement of Power Device Turn-off Switching Loss. This test method produces the true total Turn-off Energy Loss.

Operating Frequency Information

Operating frequency information for a typical device (Figure 10) is presented as a guide for estimating device performance for a specific application. Other typical frequency vs collector current (I_{CE}) plots are possible using the information shown for a typical unit in Figures 7, 8 and 9. The operating frequency plot (Figure 10) of a typical device shows f_{MAX1} or f_{MAX2} whichever is smaller at each point. The information is based on measurements of a typical device and is bounded by the maximum rated junction temperature.

f_{MAX1} is defined by $f_{MAX1} = 0.05 / t_{D(OFF)}$. $t_{D(OFF)}$ (the denominator) has been arbitrarily held to 10% of the on-state time for a 50% duty factor. Other definitions are possible. $t_{D(OFF)}$ is defined as the time between the 90% point of the trailing edge of the input pulse and the point where the collector current falls to 90% of its maximum value. Device turn-off delay can establish an additional

frequency limiting condition for an application other than T_{JMAX} . $t_{D(OFF)}$ is important when controlling output ripple under a lightly loaded condition.

f_{MAX2} is defined by $f_{MAX2} = (P_D - P_C) / W_{OFF}$. The allowable dissipation (P_D) is defined by $P_D = (T_{JMAX} - T_C) / R_{ΘJC}$. The sum of device switching and conduction losses must not exceed P_D . A 50% duty factor was used (Figure 10) so that the conduction losses (P_C) can be approximated by $P_C = (V_{CE} \times I_{CE}) / 2$. W_{OFF} is defined as the sum of the instantaneous power loss starting at the trailing edge of the input pulse and ending at the point where the collector current equals zero ($I_{CE} = 0A$).

The switching power loss (Figure 10) is defined as $f_{MAX1} \times W_{OFF}$. Turn on switching losses are not included because they can be greatly influenced by external circuit conditions and components.
