### Features

- Fast Access Time ..... 70/90ns Max
- Low Standby Current.....50µA Max
- Low Operating Current ..... 70mA Max
- Data Retention at 2.0V.....20µA Max
- TTL Compatible Inputs and Outputs
- JEDEC Approved Pinout (2716, 6116 Type)
- No Clocks or Strobes Required
- Equal Cycle and Access Time
- Single 5V Supply
- Gated Inputs
- No Pull-Up or Pull-Down Resistors Required

### Description

The HM-65162 is a CMOS 2048 x 8 Static Random Access Memory manufactured using the Intersil Advanced SAJI V process. The device utilizes asynchronous circuit design for fast cycle time and ease of use. The pinout is the JEDEC 24 pin DIP, and 32 pad 8-bit wide standard which allows easy memory board layouts flexible to accommodate a variety of industry standard PROMs, RAMs, ROMs and EPROMs. The HM-65162 is ideally suited for use in microprocessor based systems with its 8-bit word length organization. The convenient output enable also simplifies the bus interface by allowing the data outputs to be controlled independent of the chip enable. Gated inputs lower operating current and also eliminate the need for pull-up or pull-down resistors.

**NOTES:**

- Input pulse levels: 0 to 3.0V; Input rise and fall times: 5ns (max); Input and output timing reference level: 1.5V; Output load: 1 TTL gate equivalent and  $C_L = 50pF$  (min) - for  $C_L$  greater than 50pF, access time is derated by 0.15ns per pF.
- Tested at initial design and after major design changes.
- $V_{CC} = 4.5$  and 5.5V.
- TAVQV = TELQV + TAVEL.

**Timing Waveforms**

NOTE:

1.  $\overline{W}$  is high for a Read Cycle.

**FIGURE 1. READ CYCLE**

Addresses must remain stable for the duration of the read cycle. To read,  $\overline{G}$  and  $\overline{E}$  must be  $\leq V_{IL}$  and  $\overline{W} \geq V_{IH}$ . The output buffers can be controlled independently by  $\overline{G}$  while  $\overline{E}$

is low. To execute consecutive read cycles,  $\overline{E}$  may be tied low continuously until all desired locations are accessed.

NOTE:

1.  $\overline{G}$  is low throughout Write Cycle.

**FIGURE 2. WRITE CYCLE I**

To write, addresses must be stable,  $\overline{E}$  low and  $\overline{W}$  falling low for a period no shorter than TWLWH. Data is referenced with the rising edge of  $\overline{W}$ , (TDVWH and TWHDX). While addresses are changing,  $\overline{W}$  must be high. When  $\overline{W}$  falls low, the I/O pins are still in the output state for a period of TWLQZ

and input data of the opposite phase to the outputs must not be applied, (Bus contention). If  $\overline{E}$  transitions low simultaneously with the  $\overline{W}$  line transitioning low, or after the  $\overline{W}$  transition, the output will remain in a high impedance state.  $\overline{G}$  is held continuously low.

Timing Waveforms (Continued)

FIGURE 3. WRITE CYCLE II

In this write cycle  $\bar{G}$  has control of the output after a period, TGHQZ.  $\bar{G}$  switching the output to a high impedance state allows data in to be applied without bus contention after

**Low Voltage Data Retention**

Intersil CMOS RAMs are designed with battery backup in mind. Data retention voltage and supply current are guaranteed over temperature. The following rules ensure data retention:

1. Chip Enable ( $\bar{E}$ ) must be held high during data retention; within  $V_{CC} - 0.3V$  to  $V_{CC} + 0.3V$ .
2. On RAMs which have selects or output enables (e.g., S,  $\bar{G}$ ), one of the selects or output enables should be held in the deselected state to keep the RAM outputs high impedance, minimizing power dissipation.
3. Inputs which are to be held high (e.g.,  $\bar{E}$ ) must be kept between  $V_{CC} + 0.3V$  and 70% of  $V_{CC}$  during the power up and down transitions.
4. The RAM can begin operation > 55ns after  $V_{CC}$  reaches the minimum operating voltage (4.5V).
