

## Dual/Hex Low-Side Switch with Both SPI and Parallel Input Control

The 33397 is a low-side switch that is user configurable to be either two 333 mΩ outputs (dual mode) or six 900 mΩ outputs (hex mode). Each output is internally current limited and short-circuit protected. Output fault detection capability includes “off state” open loads and “on state” short-to-battery conditions. Faults for each output are latched into the fault register and serially shifted out during serial communication.

### Features

- User Configurable to be Either Two 333 mΩ Outputs (Dual Mode) or Six 900 mΩ Outputs (Hex Mode)
- Output Inductive Energy Clamps
- Parallel Input (3.3 V and 5.0 V Compatible) or Serial Peripheral Interface (SPI) Control
- 8-Bit SPI Control and Fault Diagnostics
- Short-to-Battery Detection and Shutdown with Automatic Retry
- OFF-State Open-Circuit Detection
- Programmable Overvoltage Shutdown ( $V_{PWR}$  Pin)
- Undervoltage Shutdown ( $V_{DD}$  Pin)
- Sleep Mode— $I_{DD} \leq 25 \mu\text{A}$  (1.0  $\mu\text{A}$  Typical)

## PIN CONNECTIONS

Figure 3. 33397 Pin Connections

Table 1. 33397 Pin Definitions

Pin Number	Pin Name	Definition
1, 2, 11, 12, 14, 23	A0–A5	Power outputs
3	SCLK	SPI clock input
4	SI	SPI serial input
5–8, 17–20	GND	Power and signal ground
9	SO	SPI serial output
10	$\overline{\text{CS}}$	SPI chip select
13	VDD	Supply input pin
15	$\overline{\text{EN}}$	Enable
16	P0	In hex mode, P0 controls output A0. In dual mode, P0 controls outputs A0, A4, and A5 simultaneously
21	P1	In hex mode, P1 controls output A1. In dual mode, P2 controls outputs A1, A2, and A3 simultaneously
22	P2	In hex mode, P2 controls output A2. P2 is also the mode control pin. If $0.25 \cdot V_{\text{DD}} < P2 < 0.75 \cdot V_{\text{DD}}$ for more than 10 $\mu\text{s}$ , the 33397 will change to dual mode
24	VPWR	Overvoltage threshold shutdown monitoring pin (not a power supply pin for the IC)

## ELECTRICAL CHARACTERISTICS

### MAXIMUM RATINGS

**Table 2. Maximum Ratings**

All voltages are with respect to ground unless otherwise noted.

Ratings	Symbol	Value	Unit
Power Supply Voltage	$V_{PWR}$	50	V
Logic Supply Voltage	$V_{DD}$	-0.3 to 7.0	V
Input Pin Voltage	$V_{IN}$	-0.3 to $V_{DD}+0.3$	V
ESD Voltage <sup>(1)</sup>			V
Human Body Model	$V_{ESD1}$	±2000	
Machine Model	$V_{ESD2}$	±200	
Single Pulse Output Clamp Energy			mJ
$I_O=500$ mA, $T_J=150^\circ\text{C}$ (Hex Mode)	$J_{CLAMP1}$	50	
$I_O=1.5$ A, $T_J=150^\circ\text{C}$ (Dual Mode)	$J_{CLAMP1}$	100	
Recommended SPI Operating Frequency	$f_{OP}$	3.5	MHz
Storage Temperature	$T_{STG}$	-55 to 150	$^\circ\text{C}$
Operating Junction Temperature	$T_J$	-40 to 150	$^\circ\text{C}$
Peak Package Reflow Temperature During Reflow <sup>(2), (3)</sup>	$T_{PPRT}$	Note 3	$^\circ\text{C}$
Thermal Resistance, Junction-to-Lead <sup>(4)</sup>	$R_{\theta J-L}$	15	$^\circ\text{C/W}$

**Notes**

- ESD1 performed in accordance with the Human Body Model ( $C_{ZAP}=100$  pF,  $R_{ZAP}=1500$   $\Omega$ ), ESD2 performed in accordance with the Machine Model ( $C_{ZAP}=200$  pF,  $R_{ZAP}=0$   $\Omega$ ).
- Pin soldering temperature limit is for 10 seconds maximum duration. Not designed for immersion soldering. Exceeding these limits may cause malfunction or permanent damage to the device.
- Freescale's Package Reflow capability meets Pb-free requirements for JEDEC standard J-STD-020C. For Peak Package Reflow Temperature and Moisture Sensitivity Levels (MSL), Go to [www.freescale.com](http://www.freescale.com), search by part number [e.g. remove prefixes/suffixes and enter the core ID to view all orderable parts. (i.e. MC33xxxD enter 33xxx), and review parametrics.
- Leads 5, 6, 7, 8, 17, 18, 19, and 20 are soldered to a heat-sinking ground plane. See [Figure 14](#).

## FUNCTIONAL DESCRIPTION

### INTRODUCTION

The 33397 is a versatile dual-mode low-side switch that can be output-configured as two 333 m $\Omega$  open drain outputs in the dual mode or as six 900 m $\Omega$  open drain outputs in the hex mode ( $R_{DS(ON)}$  @ 25°C).

Each open drain output has internal current limit and short-circuit protection. Current limit is typically 1.5 A, with 2.0 A maximum. The outputs can be input controlled via parallel inputs or the SPI. Three inputs provide parallel control, while

a serial 8-bit word provides SPI control of the outputs. Output fault detection capability includes OFF-state open loads and ON-state short-to-battery conditions. Individual output faults are latched into the fault register and serially shifted out during serial communication to the 33397. The 33397 has both overvoltage and undervoltage shutdown.

A low quiescent current sleep state feature can be enabled or disabled on command via the SPI port.

### FUNCTIONAL PIN DESCRIPTION

#### VDD

Logic power supply pin.

#### A0–A5

A0–A5 are the drains of the 1.2  $\Omega$  (max.) MOSFETs. They each have an internal voltage clamp of 50 V (min.) to clamp inductive loads during turn-off. When enabled, they are each internally current limited to a maximum of 2.0 A. If any output is in current limit (output voltage >3.0 V) for a time greater than  $t_{SS}$ , the output will be disabled for a time  $t_{REF}$  and then try to turn on again. When disabled, open circuits are detected if the output is less than 3.0 V for a time of  $t_{SS}$ . Either type of fault is reported as a fault on the SPI output word. If  $\overline{EN}$  input is high and SPI bit 7=1, the pull-down current sources on the outputs are disabled to minimize  $V_{DD}$  supply current.

In hex mode, all six outputs are independent. Outputs A0, A1, and A2 are controlled by either the SPI input word bits 0, 1, and 2, respectively, or parallel inputs P0, P1, and P2. Outputs A3, A4, and A5 are controlled only by SPI input word bits 3, 4, and 5, respectively.

In dual mode, outputs A0, A4, and A5 are all controlled simultaneously by input P0 or by SPI bits 0, 4, and 5. All three bits must be high to enable this output via the SPI. Outputs A1, A2, and A3 are all controlled simultaneously by input P1 or by SPI bits 1, 2, and 3. All three bits must be high to enable this output via the SPI.

#### P0–P2

In hex mode, P0 is the parallel input to control output A0. It is OR'd with SPI bit 0 to enable output A0. Either one will enable output A0. In dual mode, P0 controls outputs A0, A4, and A5 simultaneously. P0 has a pull down current of 10  $\mu$ A. It is ignored when  $\overline{EN}$  is high and bit 7=1.

In hex mode, P1 is the parallel input to control output A1. It is OR'd with SPI bit 1 to enable output A1. Either one will enable output A1. In dual mode, P1 controls outputs A1, A2, and A3 simultaneously. P1 has a pull-down current of 10  $\mu$ A. It is ignored when  $\overline{EN}$  is high and bit 7=1.

In hex mode, P2 is the parallel input to control output A2. It is OR'd with SPI bit 2 to enable output A2. Either one will enable output A2.

P2 also is used to program the 33397 to either a dual or hex output device. The 33397 will be the hex mode if P2 is biased above  $0.75 \cdot V_{DD}$  (typical) or below  $0.25 \cdot V_{DD}$  (typical). Normal 5.0 V control logic on this parallel input will maintain the 33397 in hex mode and allow control of output A2. If  $0.25 \cdot V_{DD} < P2 < 0.75 \cdot V_{DD}$  for more than 10  $\mu$ s, the 33397 will switch to dual mode. P2 has a pull-down current of 10  $\mu$ A. It is ignored when  $\overline{EN}$  is high and bit 7=1.

#### VPWR

$V_{PWR}$  is used to sense an overvoltage condition on the supply pin. When the voltage on  $V_{PWR}$  exceeds  $V_{OV}$ , all outputs are disabled for the duration of the overvoltage condition. If  $V_{PWR}$  is grounded, overvoltage shutdown is disabled.  $V_{PWR}$  threshold can be modified with an external resistor divider if higher thresholds are desired.

#### SCLK

SCLK is the clock for the serial interface.

#### SI

SI is the serial input for the SPI port. When  $\overline{CS}$  is low, SI is read on the positive edge of SCLK and SO is updated on the falling edge. When  $\overline{CS}$  is high, SI is ignored. SI has a pull-down current source to pull it low in the event of an open circuit.

#### SO

SO is the serial output of the SPI port. When  $\overline{CS}$  goes low, SO outputs bit 7 of the output word. On each falling edge of SCLK, SO will shift the next SPI output bit until on the eighth SCLK falling edge the bit present on SI during the first rising edge will appear. In this way devices can be daisy-chained to operate on a common  $\overline{CS}$ . When  $\overline{CS}$  is high, SO is high impedance.

**$\overline{\text{CS}}$** 

$\overline{\text{CS}}$  is the chip select to enable the SPI interface. When  $\overline{\text{CS}}$  is high, no SPI communication is possible. When  $\overline{\text{CS}}$  goes low, SI will be read on each rising SCLK edge and SO will shift on each SCLK falling edge. When  $\overline{\text{CS}}$  goes high, the bits present in the SPI input register will be interpreted as the SPI input command. Also when  $\overline{\text{CS}}$  goes high, all faults that were latched into the SPI output register are cleared. If faults are still present on outputs, they will be re-latched after  $t_{\text{SS}}$ .

 **$\overline{\text{EN}}$** 

$\overline{\text{EN}}$  must be low for complete IC functionality in either the dual or hex mode. When  $\overline{\text{EN}}$  transitions low while in the sleep

mode or when the IC is powered up from  $V_{\text{DD}}$ , a power-up timer of 40  $\mu\text{s}$  is started to allow the 33397 to determine which mode it is in (hex or dual). During this time all parallel inputs and serial control SPI bits will be ignored and all outputs will remain off. If  $\overline{\text{EN}}$  transitions low when not in the sleep mode, this “dead” time will not occur.

If a one was written to bit 7, the 33397 will be in the sleep mode when  $\overline{\text{EN}}$  goes high. In this mode all SPI registers are reset to zero and all faults are cleared. No fault detection is possible. The standby supply current on  $V_{\text{DD}}$  and  $V_{\text{PWR}}$  is minimized.

## TYPICAL APPLICATION

### INTRODUCTION

A voltage on the P2 input pin determines the mode. All six outputs can operate either independently (hex mode) (Figure 15) or in paralleled groups of three (dual mode) (Figure 16). In the dual mode, outputs A0, A1, and A2 are controlled by parallel inputs P0, P1, and P2, respectively, and they are also controlled by the SPI port with which they are OR'd. On the other hand, outputs A3, A4, and A5 are controlled *only* through the SPI port. When the voltage on P2 is between  $0.25 V_{DD}$  and  $0.75 V_{DD}$  (i.e., when P2 is held at an intermediate voltage, neither high nor low), the 33397 operates in the dual mode. However, the P2 pin must stay at that level for a minimum specified time. In this mode, outputs A0, A4, and A5 are all controlled in parallel by input P0. Outputs A1, A2, and A3 are all controlled in parallel by input P1. Both outputs can also be controlled via the SPI port as well, but only if the three outputs are commanded ON at the same time.

RoHS-compliant and/or Pb-free versions of Freescale products have the functionality and electrical characteristics of their non-RoHS-compliant and/or non-Pb-free counterparts. For further information, see <http://www.freescale.com> or contact your Freescale sales representative.

For information on Freescale's Environmental Products program, go to <http://www.freescale.com/epp>.

Information in this document is provided solely to enable system and software implementers to use Freescale Semiconductor products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document.

Freescale Semiconductor reserves the right to make changes without further notice to any products herein. Freescale Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Freescale Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in Freescale Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals", must be validated for each customer application by customer's technical experts. Freescale Semiconductor does not convey any license under its patent rights nor the rights of others. Freescale Semiconductor products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Freescale Semiconductor product could create a situation where personal injury or death may occur. Should Buyer purchase or use Freescale Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold Freescale Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Freescale Semiconductor was negligent regarding the design or manufacture of the part.
