

MAX5214/MAX5216

14-/16-Bit, Low-Power, Buffered Output, Rail-to-Rail DACs with SPI Interface

General Description

The MAX5214/MAX5216 are pin-compatible, 14-bit and 16-bit digital-to-analog converters (DACs). The MAX5214/MAX5216 are single-channel, low-power, buffered voltage-output DACs. The devices use a precision external reference applied through the high resistance input for rail-to-rail operation and low system power consumption. The MAX5214/MAX5216 accept a wide 2.7V to 5.5V supply voltage range. Power consumption is extremely low to accommodate most low-power and low-voltage applications. These devices feature a 3-wire SPI-/QSPI™-/MICROWIRE-/DSP-compatible serial interface to save board space and to reduce the complexity in isolated applications. The MAX5214/MAX5216 minimize the digital noise feedthrough from input to output with SCLK and DIN input buffers powered down after completion of each serial input frame. On power-up, the MAX5214/MAX5216 reset the DAC output to zero, providing additional safety for applications that drive valves or other transducers that need to be off on power-up. The DAC output is buffered resulting in a low supply current of 80μA (max) and a low offset error of ±0.25mV. A zero level applied to the $\overline{\text{CLR}}$ pin asynchronously clears the contents of the input and DAC registers and sets the DAC output to zero independent of the serial interface. The MAX5214/MAX5216 are available in an ultra-small (3mm x 5mm), 8-pin μMAX® package and are specified over the -40°C to +105°C extended industrial temperature range.

Applications

- 2-Wire Sensors
- Communication Systems
- Automatic Tuning
- Gain and Offset Adjustment
- Power Amplifier Control
- Process Control and Servo Loops
- Portable Instrumentation
- Programmable Voltage and Current Sources
- Automatic Test Equipment

Ordering Information appears at end of data sheet.

QSPI is a trademark of Motorola, Inc.

μMAX is a registered trademark of Maxim Integrated Products, Inc.

Benefits and Features

- Low Power Consumption (80μA max)
- 14-/16-Bit Resolution in a 3mm x 5mm, 8-Pin μMAX Package
- Relative Accuracy
 - ±0.40 LSB INL (MAX5214, 14-Bit typ, ±1 LSB max)
 - ±1.2 LSB INL (MAX5216, 16-Bit typ, ±4 LSB max)
- Guaranteed Monotonic Over All Operating Ranges
- Low Gain and Offset Error
- Wide 2.7V to 5.5V Supply Range
- Rail-to-Rail Buffered Output Operation
- Safe Power-On Reset (POR) to Zero DAC Output
- Fast 50MHz, 3-Wire, SPI/QSPI/MICROWIRE Compatible Serial Interface
- Schmitt-Trigger Inputs for Direct Optocoupler Interface
- Asynchronous $\overline{\text{CLR}}$ Clears DAC Output to Code 0
- High Reference Input Resistance for Power Reduction
- Buffered Voltage Output Directly Drives 10kΩ Loads

Functional Diagram

Absolute Maximum Ratings

V _{DD} to GND.....	-0.3V to +6V	Maximum Current into Any Input or Output.....	±50mA
REF, OUT, CLR to GND	-0.3V to the lower of (V _{DD} + 0.3V) and +6V	Operating Temperature Range.....	-40°C to +105°C
SCLK, DIN, CS to GND.....	-0.3V to +6V	Storage Temperature Range.....	-65°C to +150°C
Continuous Power Dissipation (T _A = +70°C)		Lead Temperature (soldering, 10s).....	+300°C
μMAX (derate at 4.8mW/°C above +70°C).....	387mW	Soldering Temperature (reflow).....	+260°C

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 1)

μMAX

Junction-to-Ambient Thermal Resistance (θ _{JA})	206°C/W
Junction-to-Case Thermal Resistance (θ _{JC})	42°C/W

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Electrical Characteristics

(V_{DD} = 2.7V to 5.5V, V_{REF} = 2.5V to V_{DD}, C_L = 60pF, R_L = 10kΩ, T_A = -40°C to +105°C, unless otherwise noted. Typical values are at T_A = +25°C.) (Note 2)

Pin Configuration

Pin Description

PIN	NAME	FUNCTION
1	REF	Reference Voltage Input. Bypass REF with a 0.1μF capacitor to GND.
2	$\overline{\text{CS}}$	Active-Low Chip-Select Input
3	SCLK	Serial-Clock Input
4	DIN	Data In
5	$\overline{\text{CLR}}$	Active-Low Asynchronous Digital-Clear Input. Drive $\overline{\text{CLR}}$ low to clear the contents of the input and DAC registers and set the DAC output to zero.
6	OUT	Buffered DAC Voltage Output
7	V _{DD}	Supply Voltage. Bypass V _{DD} with a 0.1μF capacitor to GND.
8	GND	Ground

Detailed Description

The MAX5214/MAX5216 are pin-compatible and software-compatible 14-bit and 16-bit DACs. The MAX5214/MAX5216 are single-channel, low-power, high-reference input resistance, and buffered voltage-output DACs. The MAX5214/MAX5216 minimize the digital noise feedthrough from their inputs to their outputs by powering down the SCLK and DIN input buffers after completion of each data frame. The data frames are 16-bit for the MAX5214 and 24-bit for the MAX5216. On power-up, the MAX5214/MAX5216 reset the DAC output to zero, providing additional safety for applications that drive valves or other transducers which need to be off on power-up. The MAX5214/MAX5216 contain a segmented resistor string-type DAC, a serial-in/parallel-out shift register, a DAC register, power-on-reset (POR) circuit, $\overline{\text{CLR}}$ to asynchronously clear the device independent of the serial interface, and control logic. On the falling edge of the clock (SCLK) pulse, the serial input (DIN) data is shifted into the device, MSB first.

Output Amplifier (OUT)

The MAX5214/MAX5216 include an internal buffer on the DAC output. The internal buffer provides improved load regulation and transition glitch suppression for the DAC output. The output buffer slews at 0.5V/μs and drives up to 10kΩ in parallel with 100pF. The analog supply voltage (V_{DD}) determines the maximum output voltage range of the device as V_{DD} powers the output buffer.

DAC Reference (REF)

The external reference input features a typical input impedance of 256kΩ and accepts an input voltage from +2V to V_{DD}. Connect an external voltage supply between REF and GND to apply an external reference.

Visit www.maximintegrated.com/products/references for a list of available voltage-reference devices.

Serial Interface

The MAX5214/MAX5216 3-wire serial interface is compatible with MICROWIRE, SPI, QSPI, and DSP. The interface provides three inputs: SCLK, \overline{CS} , and DIN. The chip-select input (\overline{CS}) frames the serial data loading at DIN. Following a chip-select input high-to-low transition, the data is shifted synchronously and latched into the input register on each falling edge of the serial-clock input (SCLK). Each serial word is 16-bit for the MAX5214 and 24-bit for the MAX5216. The first 2 bits are the control bits followed by 14 data bits (MSB first) for the MAX5214 and 22 data bits (MSB first) for the MAX5216 as shown in [Table 1](#) and [Table 2](#). The serial input register

transfers its contents to the input registers after loading 16/24 bits of data and updates the DAC output immediately after the data is received on the 16-/24-bit falling edge of the clock. To initiate a new data transfer, drive \overline{CS} high and keep \overline{CS} high for a minimum of 20ns before the next write sequence. The SCLK can be either high or low between \overline{CS} write pulses. [Figure 1](#) and [Figure 2](#) show the timing diagram for the complete 3-wire serial interface transmission. The MAX5216 DAC code is unipolar binary with $V_{OUT} = (\text{code}/65,535) \times V_{REF}$. The MAX5214 DAC code is unipolar binary with $V_{OUT} = (\text{code}/16,383) \times V_{REF}$. See [Table 1](#) and [Table 2](#).

Writing to the Devices

- 1) Drive \overline{CS} low, enabling the shift register.
- 2) Clock 16/24 bits of data into DIN (MSB first and LSB last), observing the specified setup and hold times.
- 3) After clocking in the last data bit, drive \overline{CS} high. \overline{CS} must remain high for 20ns before the next transmission is started.

[Figure 1](#) shows a write operation for the transmission of 16 bits. If \overline{CS} is driven high at any point prior to receiving 16 bits, the transmission is discarded.

[Figure 2](#) shows a write operation for the transmission of 24 bits. If \overline{CS} is driven high at any point prior to receiving 24 bits, the transmission is discarded.

Clear (\overline{CLR})

The MAX5214/MAX5216 feature an asynchronous active-low \overline{CLR} logic input that sets the DAC output to zero. Driving \overline{CLR} low clears the contents of both the input and DAC registers and also aborts the on-going SPI command. To allow a new SPI command, drive \overline{CLR} high.

Power-Down Mode

The MAX5214/MAX5216 feature a software-controlled power-down mode. In power-down, the output disconnects from the buffer and is grounded with one of the three selectable internal resistors. See [Table 3](#) for the selectable internal resistor values in power-down mode. The selected mode takes effect on the 16th SCLK falling edge of the MAX5214 and 24th SCLK falling edge of the MAX5216. The serial interface remains active in power-down mode. In order to abort the power-down mode selection, pull \overline{CS} high prior to the 16th (MAX5214) or 24th (MAX5216) SCLK falling edge. The contents of the DAC register remain valid while in power-down mode, allowing for the DAC to return to previous code by writing 0x8000 for the MAX5214 or 0x800000 for the MAX5216 ([Table 3](#)). A write to the write-through register causes the device to immediately exit power-down mode and transition to the requested code (see [Table 1](#) and [Table 2](#)).

Table 3. Power-Down Modes

A1	A0	DESCRIPTION	DAC OPERATION CONDITION
0	0	DAC powers up and returns to its previous code setting.	Normal operation
0	1	DAC powers down; OUT is high impedance.	Power-down
1	0	DAC powers down; OUT connects to ground through an internal 100k Ω resistor.	
1	1	DAC powers down; OUT connects to ground through an internal 1k Ω resistor.

0000 0000 0000 00XX	0V

Applications Information

Power-On Reset (POR)

When first power is applied to V_{DD} , the input registers are set to zero so the DAC output is set to code zero. To optimize DAC linearity, wait until the supplies have settled. The MAX5214/MAX5216 output voltage range is 0 to V_{REF} .

Power Supplies and Bypassing Considerations

Bypass V_{DD} with high-quality 0.1 μ F ceramic capacitors to a low-impedance ground as close as possible to the device.

Minimize lead lengths to reduce lead inductance. Connect the GND to the analog ground plane.

Layout Considerations

Digital and AC transient signals on GND can create noise at the output. Connect GND to the star ground for the DAC system. Refer the remote DAC loads to this system ground for the best possible performance. Use proper grounding techniques, such as a multilayer board with a low-inductance ground plane, or star connect all ground return paths back to the MAX5214/MAX5216 GND. Carefully lay out the traces between channels to reduce AC cross-coupling. Do not use wire-wrapped boards and sockets. Use shielding to improve noise immunity. Do not run analog and digital signals parallel to one another, especially clock signals. Avoid routing digital lines underneath the MAX5214/MAX5216 package.

Definitions

Integral Nonlinearity (INL)

INL is the deviation of the measured transfer function from a straight line drawn between two codes once offset and gain errors have been nullified.

Differential Nonlinearity (DNL)

DNL is the difference between an actual step height and the ideal value of 1 LSB. If the magnitude of the DNL is greater than -1 LSB, the DAC guarantees no missing codes and is monotonic.

Offset Error

Offset error indicates how well the actual transfer function matches the ideal transfer function at a single point. Typically, the point at which the offset error is specified is at or near the zero-scale point of the transfer function.

Gain Error

Gain error is the difference between the ideal and the actual full-scale output voltage on the transfer curve, after nullifying the offset error. This error alters the slope of the transfer function and corresponds to the same percentage error in each step.

Settling Time

The settling time is the amount of time required from the start of a transition, until the DAC output settles to the new output value within the converter's specified accuracy.

Digital Feedthrough

Digital feedthrough is the amount of noise that appears on the DAC output when the DAC digital control lines are toggled.

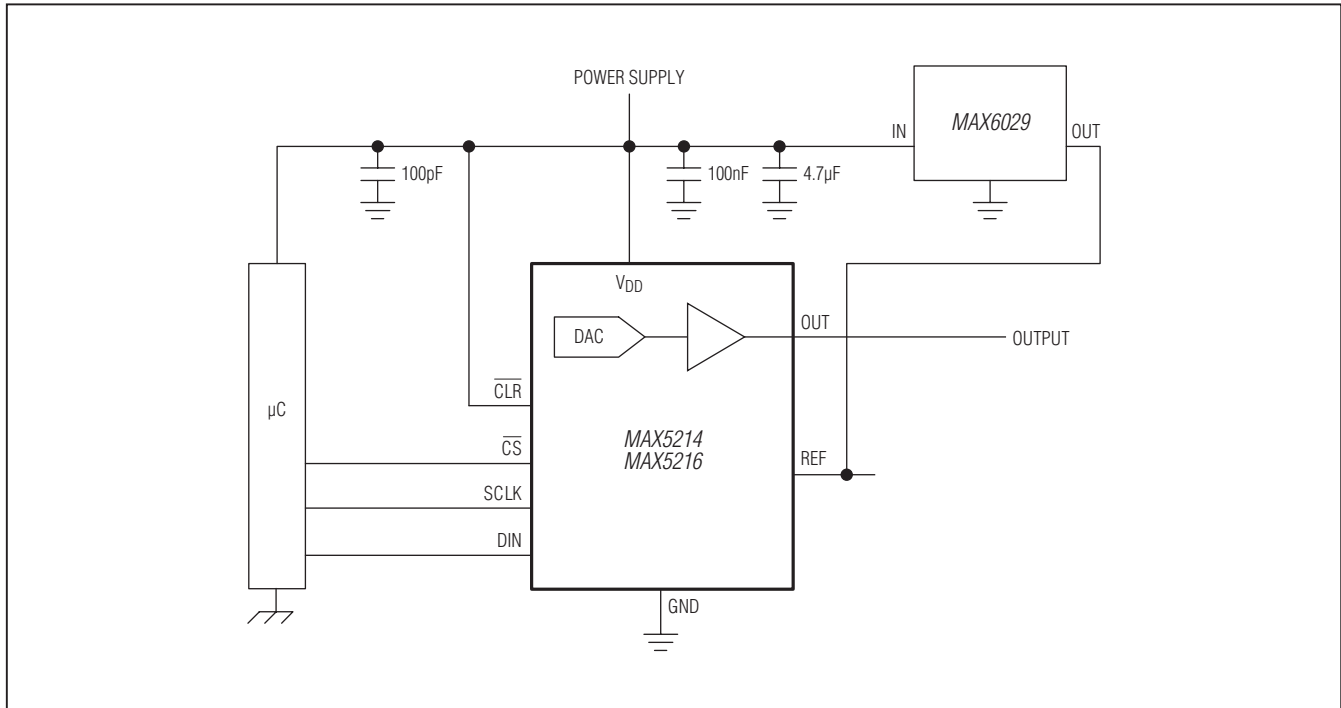

Digital-to-Analog Glitch Impulse

A major carry transition occurs at the midscale point where the MSB changes from low to high and all other bits change from high to low, or where the MSB changes from high to low and all other bits change from low to high. The duration of the magnitude of the switching glitch during a major carry transition is referred to as the digital-to-analog glitch impulse.

Digital-to-Analog Power-Up Glitch Impulse

The digital-to-analog power-up glitch is the duration of the magnitude of the switching glitch that occurs as the device exits power-down mode.
