## 3 Hall-effect sensing

### 3.1 Introduction to Hall-effect sensing

The IQS620(A) has two internal Hall-effect sensing plates (on chip). No external sensing hardware is required for Hall-effect sensing.

The Hall-effect measurement is essentially a current measurement of the induced current through the Hall-effect-sensor plates produced by the magnetic field passing perpendicular through each plate.

Advanced digital signal processing is performed to provide sensible output data.

- Two threshold levels are provided (prox & touch).
- Hall-effect output is linearized by inverting signals.
- North/South field direction indication provided.
- Differential Hall-Effect sensing:
  - Removes common mode disturbances
  - North-South field indication

### 3.2 Channel specifications

Channels 4 and 5 are dedicated to Hall-effect sensing. Channel 4 performs the positive direction measurements and channel 5 will handle all measurements in the negative direction. These two channels are used in conjunction to acquire differential Hall-effect data and will always be used as input data to the Hall-effect UI's.

There are two distinct Hall-effect user interfaces available:

- a) General Hall-effect sensing
- b) Hall-effect switch UI

### 3.5 Sensor data output and flags

The following registers can be monitored by the master to detect Hall-effect related events.

- Two bits in the **Global events (0x11)** register are dedicated to Hall-effect related output. **HALL\_COVER\_CLOSED** (bit7) will provide the status of a Hall-effect cover implementation (cover closed = 1 or cover open = 0). Bit2 will be toggled during any Hall-effect proximity detection.

## 4 Inductive sensing

### 4.1 Introduction to inductive sensing

The IQS620(A) provides inductive sensing capabilities in order to detect the presence of metal/metal-type objects. Prox and touch thresholds are widely adjustable and individual hysteresis settings are definable for each using the Hysteresis UI.

### 4.2 Channel specifications

The IQS620(A) requires both Rx sensing pins as well as the Tx pin for mutual inductive sensing.

Channels 0, 1 and/or 2 can be setup for inductive sensing although only channel 2 can be used for the Hysteresis UI which is attractive as an inductive data processing UI.

The Hysteresis UI provides superior options for prox and touch activation with filter halt and hysteresis settings.

## 5 Temperature monitoring

### 5.1 Introduction to temperature monitoring

The IQS620(A) provides temperature monitoring capabilities which can be used for temperature change detection in order to ensure the integrity of other sensing technology. The use of the temperature sensor is primarily to reseed other sensor channels to account for sudden changes in environmental conditions.

The IQS620(A) uses a linearly proportional to absolute temperature sensor for temperature data. The temperature output data is given by,

$$T = \frac{a \cdot 2^{19}}{b \cdot CH_3} + c$$

Where *a*, *b* and *c* are constants that can be determined to provide a required output data as a function of device temperature. Additionally, the channel setup must be calculated during a testing process.

**Table 5.1 Temperature calibration setting registers and ranges**

Parameter		IQS620		IQS620A	
Name	Description	Register	Range	Register	Range
<i>a</i>	<i>Multiplier</i>	0xC2	Higher nibble	1 – 16	0xC2
<i>b</i>	<i>Divider</i>		Lower nibble	1 – 16	0xC3
<i>c</i>	<i>Offset</i>	0xC3		0 – 255	0xC4

### 5.2 Channel specifications

The IQS620(A) requires only external passive components to do temperature monitoring (no additional circuitry/components required). The temperature UI will be executed using data from channel 3.

## 6 Device clock, power management and mode operation

### 6.1 Device main oscillator

The IQS620(A) has a **16MHz** main oscillator (default enabled) to clock all system functionality.

An option exists to reduce the main oscillator to 4MHz. This will result in all system timings, charge transfers and sample rates to be one-quarter of the default implementations.

To set this option this:

- As a software setting – Set the System\_Settings: bit4 = 1, via an I<sup>2</sup>C command.
- As a permanent setting – Set the OTP option in OTP Bank 0: bit2 = 1, using Azoteq USBProg program.

### 6.2 Device modes

The IQS620(A) supports the following modes of operation;

- **Normal mode** (Fixed report rate)
- **Low power mode** (Reduced report rate)
- **Ultra-low power mode** (Only channel 0 is sensed for a prox)
- **Halt mode** (Suspended/disabled)

*Note: Auto modes must be disabled to enter or exit halt mode.*

The device will automatically switch between the different operating modes by default. However, this Auto mode feature may be disabled by setting the DSBL\_AUTO\_MODE bit (Power\_mode\_settings 0xD2: bit5) to confine device operation to a specific power mode. The POWER\_MODE bits (Power\_mode\_settings 0xD2: bit4-3) can then be used to specify the desired mode of operation.

#### 6.2.1 Normal mode

Normal mode is the fully active sensing mode to function at a fixed report rate specified in the Normal mode report rate (0xD3) register. This 8-bit value is adjustable from 0ms – 255ms in intervals of 1ms.

*Note: The device's low power oscillator has an accuracy of 4ms.*

#### 6.2.2 Low power mode

Low power mode is a reduced sensing mode where all channels are sensed but at a reduced sample rate. The sample rate can be specified in the Low Power mode report rate (0xD4) register. The 8-bit value is adjustable from 0ms – 255ms in intervals of 1ms. Reduced report rates also reduce the current consumed by the sensor.

*Note: The device's low power oscillator has an accuracy of 4ms.*

#### 6.2.3 Ultra-low power mode

Ultra-low power mode is a reduced sensing mode where only channel 0 is sensed and no other channels or UI code are executed. Set the EN\_ULP\_MDE bit (Power\_mode\_settings: bit6) to enable use of the ultra-low power mode. The sample rate can be specified in the Ultra-Low Power mode report rate (0xD5) register. The 8-bit value is adjustable from 0ms – 4sec in intervals of 16ms.

Wake up will occur on prox detection on channel 0.

#### 6.2.4 Halt mode

Halt mode will suspend all sensing and will place the device in a dormant or sleep state. The device requires an I<sup>2</sup>C command from a master to explicitly change the power mode out of the halt state before any sensor functionality can continue.

## 6.2.5 Mode time

The mode time is specified in the Auto Mode Timer (0xD6) register. The 8-bit value is adjustable from 0ms – 2 min in intervals of 500ms.

## 6.3 System reset

The IQS620(A) device monitor's system resets and events.

- a) Every device power-on and reset event will set the Show Reset bit (System flags 0x10: bit7) and the master should explicitly clear this bit by setting the ACK\_RESET (bit6) in System Settings.
- b) The system events will also be indicated with the Global events register's SYS\_EVENT bit (Global events 0x11: bit5) if any system event occur such as a reset. This event will continuously trigger until the reset has been acknowledged.

## 7 Communication

### 7.1 I<sup>2</sup>C module specification

The device supports a standard two wire I<sup>2</sup>C interface with the addition of an RDY (ready interrupt) line. The communications interface of the IQS620(A) supports the following:

- Streaming data as well as event mode.
- The master may address the device at any time. If the IQS620(A) is not in a communication window, the device will return an ACK after which clock stretching may be induced until a communication window is entered. Additional communication checks are included in the main loop in order to reduce the average clock stretching time.
- The provided interrupt line (RDY) is an open-drain active low implementation and indicates a communication window.

### 7.2 I<sup>2</sup>C Read

To read from the device a *current address read* can be performed. This assumes that the address-command is already setup as desired.

#### Current Address Read

Figure 7.1 Current Address Read

If the address-command must first be specified, then a *random read* must be performed. In this case, a WRITE is initially performed to setup the address-command, and then a repeated start is used to initiate the READ section.

#### Random Read

Figure 7.2 Random Read

### 7.3 I<sup>2</sup>C Write

To write settings to the device a *Data Write* is performed. Here the Address-Command is always required, followed by the relevant data bytes to write to the device.

#### Data Write

Figure 7.3 I<sup>2</sup>C Data Write

## 7.4 Stop-bit disable option

The IQS620A part offer:

- an additional [I<sup>2</sup>C settings](#) register (0xDA) specifically added for stop-bit disable functionality,
- as well as a [RDY timeout period](#) register (0xD9) in order to set the required timeout period for termination of any communication windows (RDY = Low) if no I<sup>2</sup>C activity is present on SDA and SCL pins.

Customers using a MCU with a binary serial-encoder peripheral which is not fully I<sup>2</sup>C compatible (but provide some crude serial communication functions) can use this option to configure the IQS620A so that any auto generated stop command from the serial peripheral can be ignored by the IQS620A I<sup>2</sup>C hardware. This will restrict the IQS620A from immediately exiting a communication window during event mode (reduced communication only for events) until all required communication has been completed and a stop command can correctly be transmitted. Please refer to the figures below for serial data transmission examples.

Please note:

1. Stop-bit disable and enable must be performed at the beginning and end of a communication window. The first and last I<sup>2</sup>C register to be written to ensure no unwanted communication window termination.
2. Leaving the Stop-bit disabled will result in successful reading of registers but will not execute any commands written over I<sup>2</sup>C in a communication window being terminated after a RDY timeout and with no IQS recognised stop command.
3. The default RDY timeout period for IQS620A is purposefully long (10.24ms) for slow responding MCU hardware architectures. Please set this register according to your requirements/preference.
4. These options are only available on IQS620A parts and not for IQS620.

## 7.5 Device address and sub-addresses

The default device address is **0x44 = DEFAULT\_ADDR**.

Alternative sub-address options are definable in the following one-time programmable bits:

**OTP Bank0 (bit3; 0; bit1; bit0) = SUB\_ADDR\_0 to SUB\_ADDR\_7**

- a) Default address: **0x44 = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_0 (0000b)**
- b) Sub-address: **0x45 = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_1 (0001b)**
- c) Sub-address: **0x46 = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_2 (0010b)**
- d) Sub-address: **0x47 = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_3 (0011b)**
- e) Sub-address: **0x4C = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_4 (1000b)**
- f) Sub-address: **0x4D = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_5 (1001b)**
- g) Sub-address: **0x4E = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_6 (1010b)**
- h) Sub-address: **0x4F = DEFAULT\_ADDR (0x44)** OR **SUB\_ADDR\_7 (1011b)**

## 7.6 Additional OTP options

All one-time-programmable device options are located in OTP bank0.

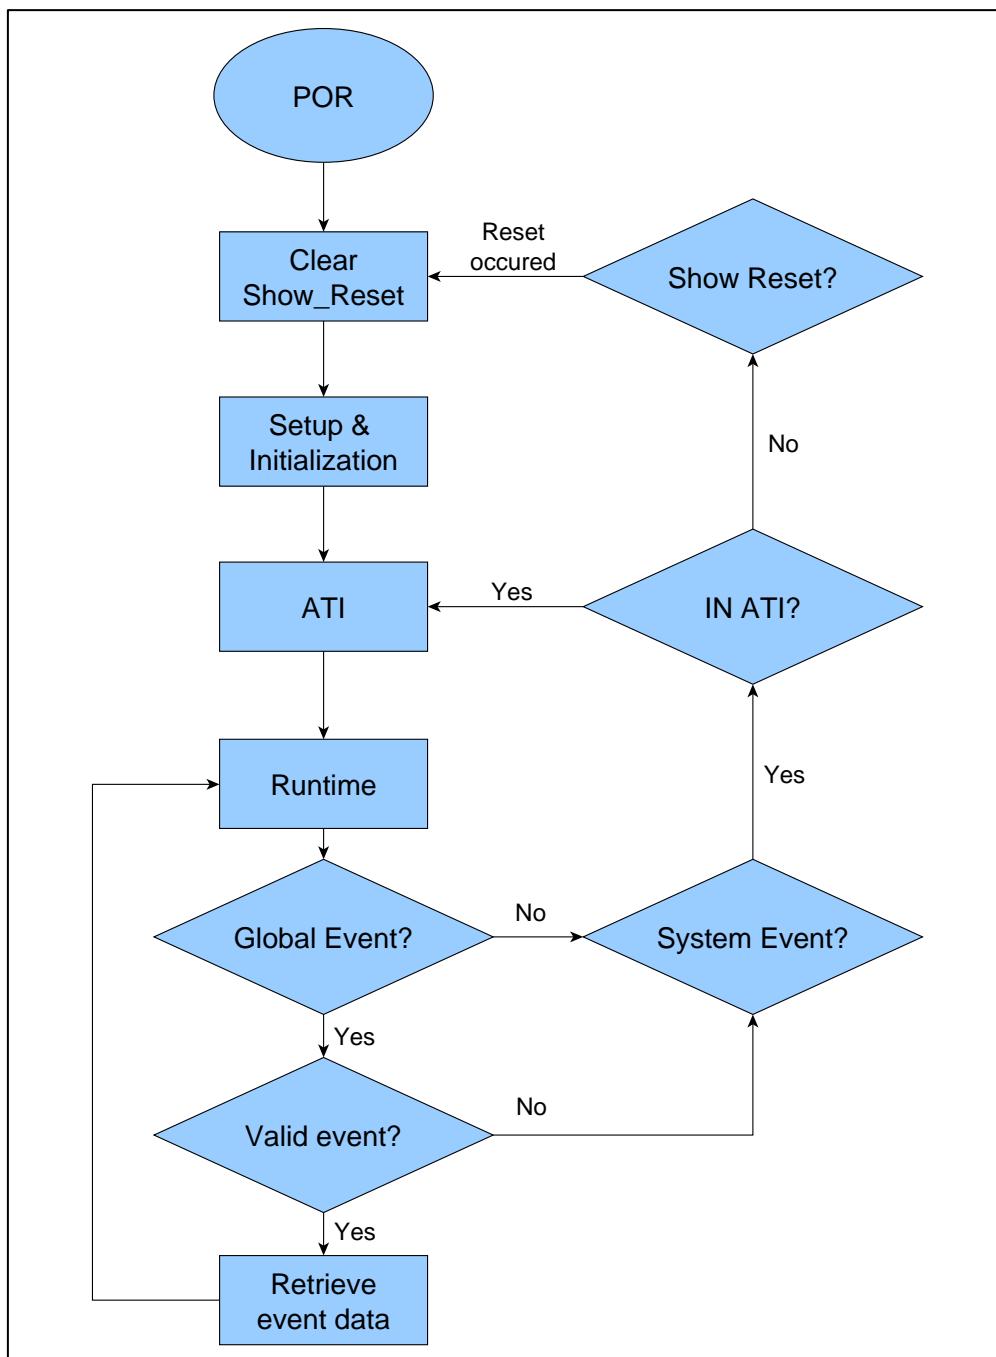

OTP bank0								
Bit Number	7	6	5	4	3	2	1	0

Bit definitions:

- Bit 7: Internal use
  - Do not set. Leave bit cleared.

  - 0: No streaming events are generated during ATI
  - 1: Communication continue as setup regardless of ATI state.
- Bit 2: Main Clock frequency selection
  - 0: Run FOSC at 16MHz
  - 1: Run FOSC at 4MHz
- Bit 3,1,0: I<sup>2</sup>C sub-address
  - I<sup>2</sup>C address = 0x44 OR SUB\_ADDR

## 7.7 Recommended communication and runtime flow diagram

The following is a basic master program flow diagram to communicate and handle the device. It addresses possible device events such as output events, ATI and system events (resets).

**Figure 7.7 Master command structure and runtime event handling flow diagram**

It is recommended that the master verifies the status of the System\_Flags0 bits to identify events and resets. Detecting either one of these should prompt the master to the next steps of handling the IQS620(A).

Streaming mode communication is used for detail sensor evaluation during prototyping and/or development phases.

Event mode communication is recommended for runtime use of the IQS620(A). This reduce the communication on the I<sup>2</sup>C bus and report only triggered events.
