

NCV4269A

LDO Linear Regulator - Micropower, DELAY, Adjustable RESET, Sense Output

5.0 V, 3.3 V, 150 mA

The NCV4269A is a 5.0 V and 3.3 V precision micropower voltage regulator with an output current capability of 150 mA.

The output voltage is accurate within $\pm 2.0\%$ with a maximum dropout voltage of 0.5 V at 100 mA. Low quiescent current is a feature drawing only 190 μA with a 1.0 mA load. This part is ideal for any and all battery operated microprocessor equipment.

Microprocessor control logic includes an active reset output RO with delay and a SI/SO monitor which can be used to provide an early warning signal to the microprocessor of a potential impending reset signal. The use of the SI/SO monitor allows the microprocessor to finish any signal processing before the reset shuts the microprocessor down.

The active Reset circuit operates correctly at an output voltage as low as 1.0 V. The Reset function is activated during the power up sequence or during normal operation if the output voltage drops outside the regulation limits.

The reset threshold voltage can be decreased by the connection of an external resistor divider to the R_{ADJ} lead. The regulator is protected against reverse battery, short circuit, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments. The device has also been optimized for EMC conditions.

Features

- 5.0 V and 3.3 V Output Voltage Options, $\pm 2.0\%$ Accuracy
- Low 190 μA Quiescent Current
- Active Reset Output Low Down to $V_{\text{Q}} = 1.0 \text{ V}$
- Adjustable Reset Threshold
- 150 mA Output Current Capability
- Fault Protection
 - ◆ +60 V Peak Transient Voltage
 - ◆ -40 V Reverse Voltage
 - ◆ Short Circuit
 - ◆ Thermal Overload
- Early Warning through SI/SO Leads
- Internally Fused Leads in SO-14 and SO-20 Packages
- Integrated Pullup Resistor at Logic Outputs (To Use External Resistors, Select the NCV4279A)
- Very Low Dropout Voltage
- Electrical Parameters Guaranteed Over Entire Temperature Range
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These are Pb-Free Devices

APPLICATION DESCRIPTION

OUTPUT REGULATOR

The output is controlled by a precision trimmed reference. The PNP output has base drive quiescent current control for regulation while the input voltage is low, preventing over saturation. Current limit and voltage monitors complement the regulator design to give safe operating signals to the processor and control circuits.

RESET OUTPUT (RO)

A reset signal, Reset Output, RO, (low voltage) is generated as the IC powers up. After the output voltage V_Q increases above the reset threshold voltage V_{RT} , the delay timer D is started. When the voltage on the delay timer V_D passes V_{UD} , the reset signal RO goes high. A discharge of the delay timer V_D is started when V_Q drops and stays below the reset threshold voltage V_{RT} . When the voltage of the delay timer V_D drops below the lower threshold voltage V_{LD} the reset output voltage V_{RO} is brought low to reset the processor.

The reset output RO is an open collector NPN transistor with an internal 20 kΩ pullup resistor connected to the output Q, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC, thereby guaranteeing that RO is valid for V_Q as low as 1.0 V.

RESET ADJUST (R_{ADJ})

The reset threshold V_{RT} can be decreased from a typical value of 4.65 V (3.04 V for 3.3 V Version) to as low as 3.5 V (2.3 V for 3.3 V Version) by using an external voltage divider connected from the Q lead to the pin R_{ADJ} , as shown in Figure 34. The resistor divider keeps the voltage above the $V_{RADJ,TH}$ (typical 1.35 V) for the desired input voltages, and overrides the internal threshold detector. Adjust the voltage divider according to the following relationship:

$$V_{RT} = V_{RADJ,TH} \cdot (R_{ADJ1} + R_{ADJ2}) / R_{ADJ2} \quad (\text{eq. 1})$$

If the reset adjust option is not needed, the R_{ADJ} pin should be connected to GND causing the reset threshold to go to its default value.

RESET DELAY (D)

The reset delay circuit provides a delay (programmable by capacitor C_D) on the reset output lead RO. The delay lead D provides charge current $I_{D,C}$ (typically 6.5 μA for 5 V Version or 4.3 μA for 3.3 V Version) to the external delay capacitor C_D during the following times:

1. During Powerup (once the regulation threshold has been exceeded).
2. After a reset event has occurred and the device is back in regulation. The delay capacitor is set to discharge when the regulation (V_{RT} , reset threshold voltage) has been violated. When the delay capacitor discharges to V_{LD} , the reset signal RO pulls low.

SETTING THE DELAY TIME

The delay time is set by the delay capacitor C_D and the charge current I_D . The time is measured by the delay capacitor voltage charging from the low level of V_{DSAT} to the higher level V_{UD} . The time delay follows the equation:

$$t_d = [C_D (V_{UD} - V_{D,SAT})] / I_{D,C} \quad (\text{eq. 2})$$

Example (5 V Version):

Using $C_D = 100 \text{ nF}$.

Use the typical value for $V_{D,SAT} = 0.1 \text{ V}$.

Use the typical value for $V_{UD} = 1.8 \text{ V}$.

Use the typical value for Delay Charge Current $I_D = 6.5 \mu\text{A}$.

$$t_d = [100 \text{ nF} (1.8 - 0.1 \text{ V})] / 6.5 \mu\text{A} = 26.2 \text{ ms} \quad (\text{eq. 3})$$

* C_1 required if regulator is located far from the power supply filter.

** C_Q - minimum cap required for stability is 2.2 μF while higher over/under-shoots may be expected. Cap must operate at minimum temperature expected.

Figure 34. Application Diagram

SENSE INPUT (SI) / SENSE OUTPUT (SO) VOLTAGE MONITOR

An on-chip comparator is available to provide early warning to the microprocessor of a possible reset signal (Figure 4). The output is from an open collector driver with an internal 20 kΩ pull up resistor to output Q. The reset signal typically turns the microprocessor off instantaneously. This can cause unpredictable results with the microprocessor. The signal received from the SO pin will allow the microprocessor time to complete its present task before shutting down. This function is performed by a comparator referenced to the band gap voltage. The actual trip point can be programmed externally using a resistor divider to the input monitor SI (Figure 34). The values for R_{SI1} and R_{SI2} are selected for a typical threshold of 1.20 V on the SI Pin.

SIGNAL OUTPUT

Figure 35 shows the SO Monitor timing waveforms as a result of the circuit depicted in Figure 34. As the output voltage (V_Q) falls, the monitor threshold (V_{SI,Low}), is crossed. This causes the voltage on the SO output to go low sending a warning signal to the microprocessor that a reset signal may occur in a short period of time. T_{WARNING} is the time the microprocessor has to complete the function it is currently working on and get ready for the reset shutdown signal. When the voltage on the SO goes low and the RO stays high the current consumption is typically 560 μA at 1 mA load current.

Figure 35. SO Warning Waveform Time Diagram

STABILITY CONSIDERATIONS

The input capacitor C₁ in Figure 34 is necessary for compensating input line reactance. Possible oscillations caused by input inductance and input capacitance can be damped by using a resistor of approximately 1.0 Ω in series with C₁.

The output or compensation capacitor helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures

(–25°C to –40°C), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer’s data sheet usually provides this information.

The 10 μF output capacitor C_O shown in Figure 34 should work for most applications; however, it is not necessarily the optimized solution. Stability is guaranteed at C_O is min 2.2 μF and max ESR is 10 Ω. There is no min ESR limit which was proved with MURATA’s ceramic caps GRM31MR71A225KA01 (2.2 μF, 10 V, X7R, 1206) and GRM31CR71A106KA01 (10 μF, 10 V, X7R, 1206) directly soldered between output and ground pins.

CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 34) is:

$$P_{D(max)} = [V_{I(max)} - V_{Q(min)}]I_{Q(max)} + V_{I(max)}I_q \quad (\text{eq. 4})$$

where:

V_{I(max)} is the maximum input voltage,

V_{Q(min)} is the minimum output voltage,

I_{Q(max)} is the maximum output current for the application,

and I_q is the quiescent current the regulator consumes at I_{Q(max)}.

Once the value of P_{D(max)} is known, the maximum permissible value of R_{θJA} can be calculated:

$$R_{\theta JA} = (150^{\circ}\text{C} - T_A) / P_D \quad (\text{eq. 5})$$

The value of R_{θJA} can then be compared with those in the package section of the data sheet. Those packages with R_{θJA}’s less than the calculated value in equation 2 will keep the die temperature below 150°C. In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required. The current flow and voltages are shown in the Measurement Circuit Diagram.

HEATSINKS

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of R_{θJA}:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \quad (\text{eq. 6})$$

where:

R_{θJC} = the junction-to-case thermal resistance,

R_{θCS} = the case-to-heat sink thermal resistance, and

R_{θSA} = the heat sink-to-ambient thermal resistance.

R_{θJC} appears in the package section of the data sheet. Like R_{θJA}, it too is a function of package type. R_{θCS} and R_{θSA} are functions of the package type, heatsink and the interface between them. These values appear in data sheets of heatsink manufacturers. Thermal, mounting, and heatsinking considerations are discussed in the ON Semiconductor application note AN1040/D, available on the ON Semiconductor website.

SOIC-8 EP CASE 751AC ISSUE E

DATE 05 OCT 2022

NOTES:

1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M, 1994.
2. CONTROLLING DIMENSION: MILLIMETERS
3. DIMENSION b DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE PROTRUSION SHALL BE 0.004 IN EXCESS OF MAXIMUM MATERIAL CONDITION.
4. DIMENSION D DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS, OR GATE BURRS. MOLD FLASH, PROTRUSIONS, OR GATE BURRS SHALL NOT EXCEED 0.006 PER SIDE. DIMENSION E1 DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSION. INTERLEAD FLASH OR PROTRUSION SHALL NOT EXCEED 0.010 mm PER SIDE.
5. THE PACKAGE TOP MAY BE SMALLER THAN THE PACKAGE BOTTOM. DIMENSIONS D AND E1 ARE DETERMINED AT THE OUTERMOST EXTREMES OF THE PLASTIC BODY AT DATUM H.
6. DATUMS A AND B ARE TO BE DETERMINED AT DATUM H.
7. DIMENSIONS b AND c APPLY TO THE FLAT SECTION OF THE LEAD BETWEEN 0.10 TO 0.25 FROM THE LEAD TIP.
8. A1 IS DEFINED AS THE VERTICAL DISTANCE FROM THE SEATING PLANE TO THE LOWEST POINT ON THE PACKAGE BODY.
