

4K x 8 Dual-Port Static RAMs and 4K x 8 Dual-Port Static RAM with Semaphores

Features

- 0.8-micron BiCMOS for high performance
- · High-speed access
 - -15 ns (commercial)
 - -25 ns (military)
- Automatic power-down
- Fully asynchronous operation
- 7B1342 includes semaphores
- 7B134 available in 48-pin DIP
- 7B135/7B1342 available in 52-pin LCC/PLCC

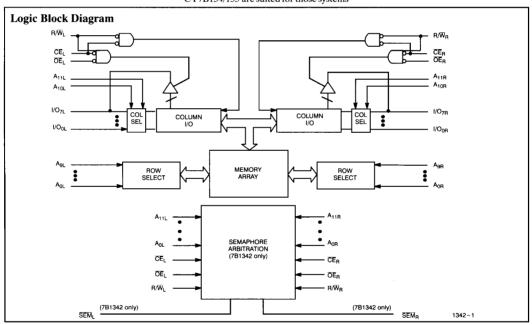

Functional Description

The CY7B134, CY7B135, and CY7B1342 are high-speed BiCMOS 4K x 8 dual-port static RAMs. The CY7B1342 includes semaphores that provide a means to allocate portions of the dual-port RAM or any shared resource. Two ports are provided permitting independent, asynchronous access for reads and writes to any location in memory. Application areas include interprocessor/multiprocessor designs, communications status buffering, and dual-port video/graphics memory.

Each port has independent control pins: chip enable (\overline{CE}), read or write enable (R/W), and output enable (\overline{OE}). The CY7B134/135 are suited for those systems

that do not require on-chip arbitration or are intolerant of wait states. Therefore, the user must be aware that simultaneous access to a location is possible. Semaphores are offered on the CY7B1342 to assist in arbitrating between ports. The semaphore logic is comprised of eight shared latches. Only one side can control the latch (semaphore) at any time. Control of a semaphore indicates that a shared resource is in use. An automatic power-down feature is controlled independently on each port by a chip enable (CE) pin or SEM pin (CY7B1342 only).

The CY7B134 is available in 48-pin DIP. The CY7B135 and CY7B1342 are available in 52-pin LCC/PLCC.

Pin Configurations

Pin Definitions

Left Port	Right Port	Description
A _{0L-11L}	A _{0R-11R}	Address Lines
<u>CE</u> L	CER	Chip Enable
Ō Ē L	OE _R	Output Enable
R/\overline{W}_L	R/W _R	Read/Write Enable
SEM _L (CY7B1342 only)	SEM _R (CY7B1342 only)	Semaphore Enable. When asserted LOW, allows access to eight semaphores. The three least significant bits of the address lines will determine which semaphore to write or read. The $1/O_0$ pin is used when writing to a semaphore. Semaphores are requested by writing a 0 into the respective location.

- Notes:
 7. See the last page of this specification for Group A subgroup testing information.
- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance
- At any given temperature and voltage condition for any given device, t_{HZCE} is less than t_{LZCE} and t_{HZOE} is less than t_{LZOE} .
- 10. Test conditions used are Load 3.
 11. For information on port-to-port delay through RAM cells from writing port to reading port, refer to Read Timing with Port-to-Port Delay waveform.
- 12. Semaphore timing applies only to CY7B1342.

Either Port Address Access

Read Cycle No. 2[13, 15]

Read Timing with Port-to-Port Delay[16]

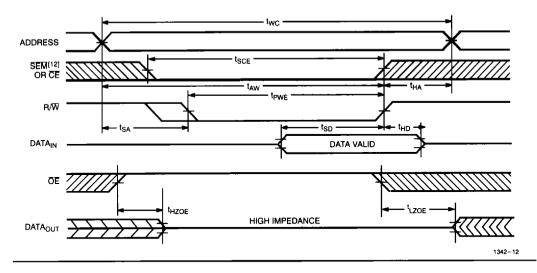

- Notes: 13. R/\overline{W} is HIGH for read cycle.
- 14. Device is continuously selected, $\overline{CE} = V_{IL}$ and $\overline{OE} = V_{IL}$.
- 15. Address valid prior to or coincident with $\overline{\text{CE}}$ transition LOW.
- 16. $\overline{CE}_L = \overline{CE}_R = LOW$; $R/\overline{W}_L = HIGH$

Switching Waveforms (continued)

Write Cycle No. 1: \overline{OE} Three-States Data I/Os (Either Port)[17, 18, 19]

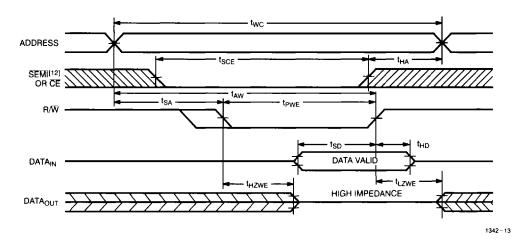

- Notes:

 17. The internal write time of the memory is defined by the overlap of CE or SEM LOW and R/W LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.
- 18. R/W must be HIGH during all address transactions.
- 19. If OE is LOW during a R/W controlled write cycle, the write pulse width must be the larger of tpwE or (tHZWE + tSD) to allow the I/O drivers to turn off and data to be placed on the bus for the required tSD. If OE is HIGH during a R/W controlled write cycle (as in this example), this requirement does not apply and the write pulse can be as short as the specified tpwE.

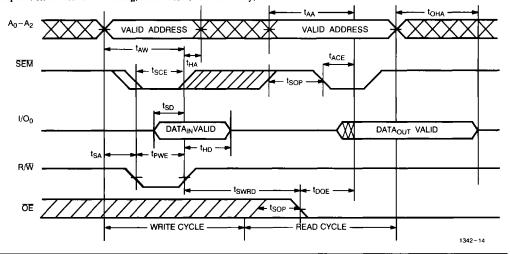

Switching Waveforms (continued)

Write Cycle No. 2: R/W Three-States Data I/Os (Either Port) $^{[18,\,20]}$

Semaphore Read After Write Timing, Either Side (CY7B1342 only) $^{\left\lceil 21\right\rceil }$

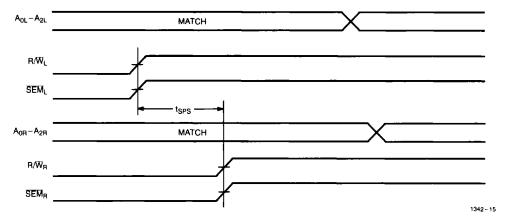

Notes:
20. Data I/O pins enter high-impedance when \overline{OE} is held I.OW during write. 21. $\overline{CE} = HIGH$ for the duration of the above timing (both write and read cycle).

Switching Waveforms (continued)

Timing Diagram of Semaphore Contention (CY7B1342 only)[22, 23, 24]

Notes:
22. $I/O_{0R} = I/O_{0L} = LOW$ (request semaphore); $\overline{CE}_R = \overline{CE}_L = HIGH$.
23. Semaphores are reset (available to both ports) at cycle start.
24. If t_{SPS} is violated, it is guaranteed that only one side will gain access to the semaphore.

Architecture

The CY7B134 and CY7B135 consist of an array of 4K words of 8 bits each of dual-port RAM cells, 1/O and address lines, and control signals (ČE, ŌE, R/W). Two semaphore control pins exist for the CY7B1342 (ŠEM_{LR}).

Functional Description

Write Operation

Data must be set up for a duration of t_{SD} before the rising edge of R/\overline{W} in order to guarantee a valid write. Since there is no on-chip arbitration, the user must be sure that a specific location will not be accessed simultaneously by both ports or erroneous data could result. A write operation is controlled by either the \overline{OE} pin (see Write Cycle No. 1 timing diagram) or the R/\overline{W} pin (see Write Cycle No. 2 timing diagram). Data can be written t_{HZOE} after the \overline{OE} is deasserted or t_{HZWE} after the falling edge of R/\overline{W} . Required inputs for write operations are summarized in Table 1.

If a location is being written to by one port and the opposite port attempts to read the same location, a port-to-port flowthrough delay is met before the data is valid on the output. Data will be valid on the port wishing to read the location $t_{\rm DDD}$ after the data is presented on the writing port.

Read Operation

When reading the device, the user must assert both the \overline{OE} and \overline{CE} pins. Data will be available t_{ACE} after \overline{CE} or t_{DOE} after \overline{OE} are asserted. If the user of the CY7B1342 wishes to access a semaphore, the SEM pin must be asserted instead of the \overline{CE} pin. Required inputs for read operations are summarized in Table 1.

Semaphore Operation

The CY7B1342 provides eight semaphore latches which are separate from the dual port memory locations. Semaphores are used to reserve resources which are shared between the two ports. The state of the semaphore indicates that a resource is in use. For example, if the left port wants to request a given resource, it sets a latch by writing a zero to a semaphore location. The left port then verifies its success in setting the latch by reading it. After writing to the semaphore, SEM or OE must be deasserted for t_{SOP} before at-tempting to read the semaphore. The semaphore value will be available t_{SWRD} + t_{DOE} after the rising edge of the semaphore write. If the left port was successful (reads a zero), it assumes control over the shared resource, otherwise (reads a one) it assumes the right port has control and continues to poll the semaphore. When the right side has relinquished control of the semaphore (by writing a one), the left side will succeed in gaining control of the semaphore. If the left side no longer requires the semaphore, a one is written to cancel its request.

Semaphores are accessed by asserting SEM LOW. The SEM pin functions as a chip enable for the semaphore latches. CE must remain HIGH during SEM LOW. A_{0-2} represents the semaphore address. OE and R/W are used in the same manner as a normal memory access. When writing or reading a semaphore, the other address pins have no effect.

When writing to the semaphore, only I/O₀ is used. If a 0 is written to the left port of an unused semaphore, a one will appear at the same semaphore address on the right port. That semaphore can now only be modified by the side showing a zero (the left port in this case). If the left port now relinquishes control by writing a one to the semaphore, the semaphore will be set to one for both sides. However, if the right port had requested the semaphore (written a zero) while the left port had control, the right port would immediately own the semaphore. Table 2 shows sample semaphore operations.

When reading a semaphore, all eight data lines output the semaphore value. The read value is latched in an output register to prevent the semaphore from changing state during a write from the other port. If both ports request a semaphore control by writing a 0 to a semaphore within tsps of each other, it is guaranteed that only one side will gain access to the semaphore.

Initialization of the semaphore is not automatic and must be reset during initialization program at power-up. All semaphores on both sides should have a one written into them at initialization from both sides to assure that they will be free when needed.

Table 1. Non-Contending Read/Write

	lnį	outs		Outputs	
CE	R/W	ŌĒ	SEM	I/O ₀ - I/O ₇	Operation
