# UC3842/UC3843/UC3844/UC3845
SMPS Controller

Features

- Low Start up Current
- Maximum Duty Clamp
- UVLO With Hysteresis
- Operating Frequency up to 500KHz

Description

The UC3842/UC3843/UC3844/UC3845 are fixed frequencycurrent-mode PWM controller. They are specially designed for Off-Line and DC to DC converter applications with minimum external components. These integrated circuits feature a trimmed oscillator for precise duty cycle control, a temperature compensated reference, high gain error amplifier, current sensing comparator and a high current totempole output for driving a Power MOSFET. The UC3842 and UC3844 have UVLO thresholds of 16V (on) and 10V (off). The UC3843 and UC3845 are 8.5V(on) and 7.9V (off). The UC3842 and UC3843 can operate within 100% duty cycle. The UC3844 and UC3845 can operate with 50% duty cycle.

3. These parameters, although guaranteed, are not 100 tested in production.

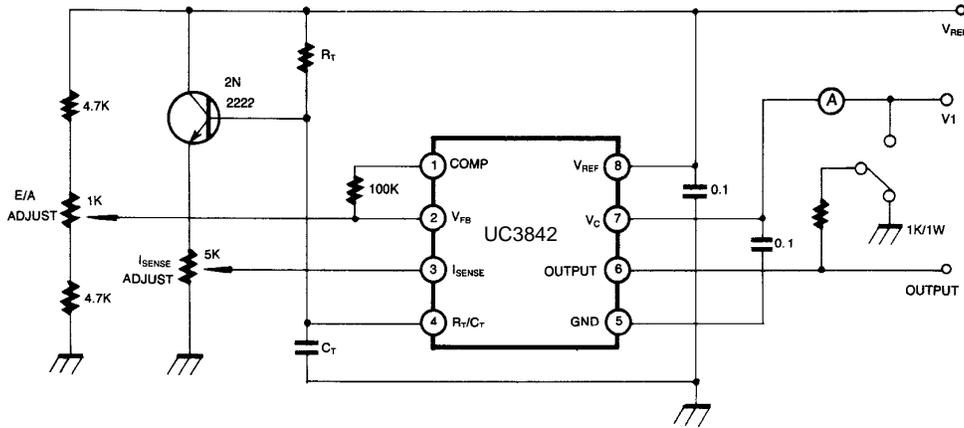

Figure 1. Open Loop Test Circuit

High peak currents associated with capacitive loads necessitate careful grounding techniques Timing and bypass capacitors should be connected close to pin 5 in a single point ground. The transistor and 5kΩ potentiometer are used to sample the oscillator waveform and apply an adjustable ramp to pin 3.
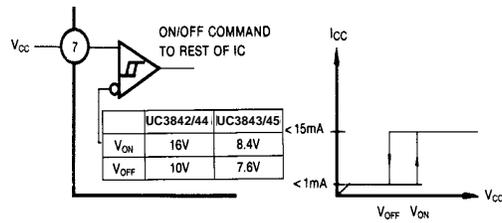

Figure 2. Under Voltage Lockout

During Under-Voltage Lock-Out, the output driver is biased to a high impedance state. Pin 6 should be shunted to ground with a bleeder resistor to prevent activating the power switch with output leakage current.

Error amp can source or sink up to 0.5mA
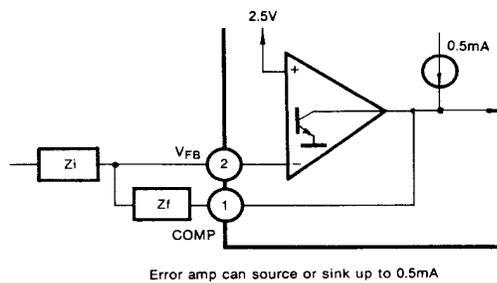

Figure 3. Error Amp Configuration
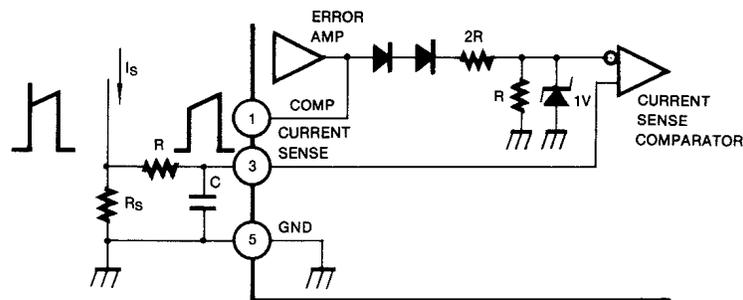

Figure 4. Current Sense Circuit

Peak current (I_S) is determined by the formula:

$$I_S(MAX) = \frac{1.0V}{R_S}$$

A small RC filter may be required to suppress switch transients.
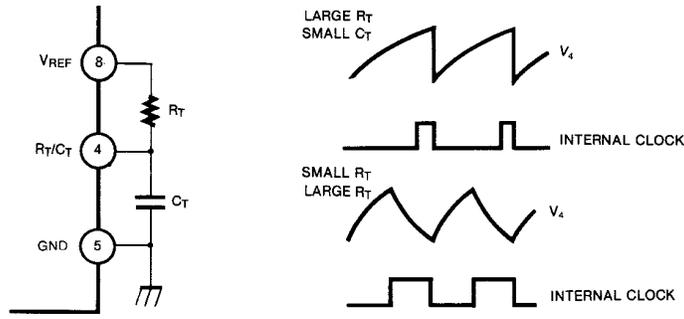

Figure 5. Oscillator Waveforms and Maximum Duty Cycle

Oscillator timing capacitor, C_T, is charged by V_{REF} through R_T and discharged by an internal current source. During the discharge time, the internal clock signal blanks the output to the low state. Selection of R_T and C_T therefore determines both oscillator frequency and maximum duty cycle. Charge and discharge times are determined by the formulas:

$$t_c = 0.55\ R_T\ C_T$$

$$t_D = R_T C_T l_n\left(\frac{0.0063 R_T - 2.7}{0.0063 R_T - 4}\right)$$

Frequency, then, is: $f = (t_c + t_d)^{-1}$

$$For\ RT > 5K\Omega, f = \frac{1.8}{R_T C_T}$$
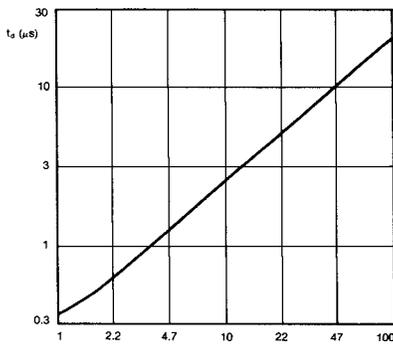

Figure 6. Oscillator Dead Time & Frequency

(Deadtime vs C_T RT > 5kΩ)
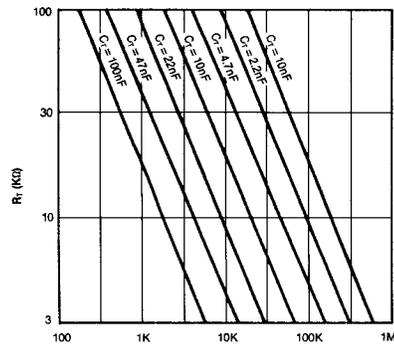

**Figure 7. Timing Resistance vs Frequency**
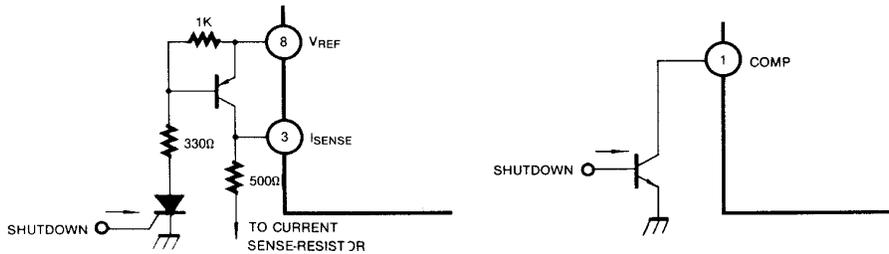

Figure 8. Shutdown Techniques

Shutdown of the UC3842 can be accomplished by two methods; either raise pin 3 above 1V or pull pin 1 below a voltage two diode drops above ground. Either method causes the output of the PWM comparator to be high (refer to block diagram). The PWM latch is reset dominant so that the output will remain low until the next clock cycle after the shutdown condition at pins 1 and/or 3 is removed. In one example, an externally latched shutdown may be accomplished by adding an SCR which will be reset by cycling V$_{CC}$ below the lower UVLO threshold. At this point the reference turns off, allowing the SCR to reset.
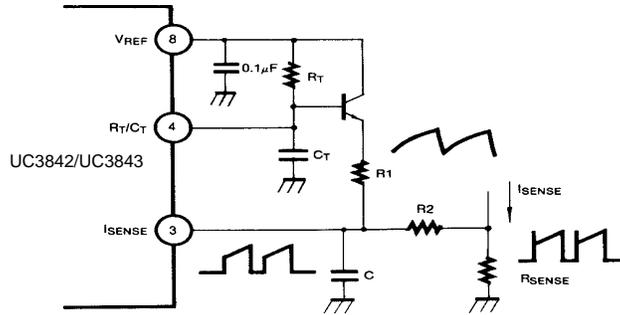

Figure 9. Slope Compensation

A fraction of the oscillator ramp can be resistively summed with the current sense signal to provide slope compensation for converters requiring duty cycles over 50%. Note that capacitor, C$_T$, forms a filter with R2 to suppress the leading edge switch spikes.
