

## Frequency Timing Generator for Dual Server/Workstation Systems

### General Description

The ICS932S200 is a dual CPU clock generator for serverworks HE-T, HE-SL-T, LE-T chipsets for P III type processors in a Dual-CPU system. Single ended CPU clocks provide faster than 1.5V/ns transition times by parallel connection of 2 CPU pins to each processor.

Spread Spectrum may be enabled by driving the SPREAD# pin active. Spread spectrum typically reduces system EMI by 8dB to 10dB. This simplifies EMI qualification without resorting to board design iterations or costly shielding. The **ICS932S200** employs a proprietary closed loop design, which tightly controls the percentage of spreading over process and temperature variations.

## ICS932S200 Power Management Features:

CPU_STOP#	PD#	PCI_STOP#	CPUCLK	IOAPIC	3V66	PCI	PCI_F	REF. 48MHz	Osc	VCOs
X	0	X	LOW	LOW	LOW	LOW	LOW	LOW	OFF	OFF

1	1	1	ON	ON	ON	ON	ON	ON	ON	ON

**Note:**

1. LOW means outputs held static LOW as per latency requirement next page.
2. On means active.
3. PD# pulled Low, impacts all outputs including REF and 48 MHz outputs.
4. All 3V66 as well as all CPU clocks should stop cleanly when CPU\_STOP# is pulled LOW.
5. IOAPIC, REF, 48 MHz signals are not controlled by the CPU\_STOP# functionality and are enabled all in all conditions except PD# = LOW

## Power Management Requirements:

Signal	Signal State	Latency
		No. of rising edges of PCICLK
CPU_STOP	0 (disabled)	1
	1 (enabled)	1
PCI_STOP#	0 (disabled)	1
	1 (enabled)	1
PD#	1 (normal operation)	3mS
	0 (power down)	2max.

### Note:

1. Clock on/off latency is defined in the number of rising edges of free running PCICLKs between the clock disable goes low/high to the first valid clock comes out of the device.
2. Power up latency is when PWR\_DWN# goes inactive (high to when the first valid clocks are driven from the device).

## CPU\_STOP# Timing Diagram

CPU\_STOP# is an asynchronous input to the clock synthesizer. It is used to turn off the CPU and 3V66 clocks for low power operation. CPU\_STOP# is asserted asynchronously by the external clock control logic with the rising edge of free running PCI clock (and hence CPU clock) and must be internally synchronized to the external output. All other clocks will continue to run while the CPU clocks are disabled. The CPU clocks must always be stopped in a low state and started in such a manner as to guarantee that the high pulse width is a full pulse.

### Notes:

1. All timing is referenced to the internal CPUCLK.
2. The internal label means inside the chip and is a reference only. This in fact may not be the way that the control is designed.
3. 3V66 clocks also stop/start before
4. PD# and PCI\_STOP# are shown in a high state.
5. Diagrams shown with respect to 133MHz. Similar operation when CPU is 100MHz

### PCI\_STOP# Timing Diagram

PCI\_STOP# is an input to the clock synthesizer and must be made synchronous to the clock driver PCICLK\_F output. It is used to turn off the PCI clocks for low power operation. PCI clocks are required to be stopped in a low state and started such that a full high pulse width is guaranteed. **ONLY one rising edge of PCICLK\_F is allowed** after the clock control logic switched for the PCI outputs to become enabled/disabled.

**Notes:**

- 1. All timing is referenced to CPUCLK.
- 2. Internal means inside the chip.
- 3. All other clocks continue to run undisturbed.
- 4. PD# and CPU\_STOP# are shown in a high state.
- 5. Diagrams shown with respect to 133MHz. Similar operation when CPU is 100MHz.

## PD# Timing Diagram

The power down selection is used to put the part into a very low power state without turning off the power to the part. PD# is an asynchronous active low input. This signal needs to be synchronized internal to the device prior to powering down the clock synthesizer.

Internal clocks are not running after the device is put in power down. When PD# is active low all clocks need to be driven to a low value and held prior to turning off the VCOs and crystal. The power up latency needs to be less than 3 mS. The power down latency should be as short as possible but conforming to the sequence requirements shown below. PCI\_STOP# and CPU\_STOP# are considered to be don't cares during the power down operations. The REF and 48MHz clocks are expected to be stopped in the LOW state as soon as possible. Due to the state of the internal logic, stopping and holding the REF clock outputs in the LOW state may require more than one clock cycle to complete.

### Notes:

1. All timing is referenced to the Internal CPUCLK (defined as inside the ICS932S200 device).
2. As shown, the outputs Stop Low on the next falling edge after PD# goes low.
3. PD# is an asynchronous input and metastable conditions may exist. This signal is synchronized inside this part.
4. The shaded sections on the VCO and the Crystal signals indicate an active clock.
5. Diagrams shown with respect to 133MHz. Similar operation when CPU is 100MHz.

### Additional Info

The ICS932S200 is a dual CPU clock generator for serverworks HE-T, HE-SL-T, LE-T chipsets for P III type processors in a Dual-CPU system. Single ended CPU clocks provide faster than 1.5V/ns transition times by parallel connection of 2 CPU pins to each processor. Spread Spectrum may be enabled by driving the SPREAD# pin active. Spread spectrum typically reduces system EMI by 8dB to 10dB. This simplifies EMI qualification without resorting to board design iterations or costly shielding. The ICS932S200 employs a proprietary closed loop design, which tightly controls the percentage of spreading over process and temperature variations.
