DSP56302A

Advance Information 24-BIT GENERAL PURPOSE DIGITAL SIGNAL PROCESSOR

The DSP56302A is a member of the DSP56300 core family of programmable CMOS Digital Signal Processors (DSPs). This family uses a high performance, single-clock-cycle-per-instruction engine providing a two-fold performance increase over Motorola's popular DSP56000 core, while retaining code compatibility. Significant architectural enhancements in the DSP56300 family include a barrel shifter, 24-bit addressing, instruction cache, and Direct Memory Access (DMA). The DSP56302A offers 66/80/100 MIPS at 3.0–3.6 V using an internal 66/80/100 MHz clock. The large on-chip memories can support wireless infrastructure and local loop applications and allow the chip to be used for RAM-based emulation of low-cost ROM-based solutions. The DSP56300 core family offers a new level of performance in speed and power provided by its rich instruction set and low power dissipation, enabling a new generation of wireless, telecommunications, and multimedia products.

Data Sheet Conventions

This data sheet uses the following conventions:

OVERBAR	Used to indicate a signal that is active when pulled low (For example, the $\overline{\text{RESET}}$ pin is active when low.)					
"asserted"	Means that a high tru signal is low	Means that a high true (active high) signal is high or that a low true (active low) signal is low				
"deasserted"	Means that a high tru signal is high	ie (active high) signa	al is low or that a low	true (active low)		
Examples:	Signal/Symbol	Logic State	Signal State	Voltage ¹		
	PIN	True	Asserted	$V_{\rm IL}/V_{\rm OL}$		
	PIN	False	Deasserted	$V_{\rm IH}/V_{\rm OH}$		
	PIN	True	Asserted	$V_{\rm IH}/V_{\rm OH}$		
	PIN False Deasserted $V_{\rm IL}/V_{\rm IL}$					

Note: Values for $V_{\rm Hz}$ $V_{\rm OL}$, $V_{\rm Hz}$, and $V_{\rm OH}$ are defined by individual product specifications.

FEATURES

High Performance DSP56300 Core

- 66/80/100 Million Instructions Per Second (MIPS) with a 66/80/100 MHz clock at 3.0–3.6 V
- Object code compatible with the DSP56000 core
- Highly parallel instruction set
- Data Arithmetic Logic Unit (Data ALU)
 - Fully pipelined 24 x 24-bit parallel Multiplier-Accumulator (MAC)
 - 56-bit parallel barrel shifter (fast shift and normalization; bit stream generation and parsing)
 - Conditional ALU instructions
 - 24-bit or 16-bit arithmetic support under software control
- Program Control Unit (PCU)
 - Position Independent Code (PIC) support
 - Addressing modes optimized for DSP applications (including immediate offsets)
 - On-chip instruction cache controller
 - On-chip memory-expandable hardware stack
 - Nested hardware DO loops
 - Fast auto-return interrupts
- Direct Memory Access (DMA)
 - Six DMA channels supporting internal and external accesses
 - One-, two-, and three-dimensional transfers (including circular buffering)
 - End-of-block-transfer interrupts
 - Triggering from interrupt lines and all peripherals
- Phase Lock Loop (PLL)
 - Allows change of low power Divide Factor (DF) without loss of lock
 - Output clock with skew elimination

Features

- Hardware debugging support
 - On-Chip Emulation (OnCE™) module
 - Joint Action Test Group (JTAG) Test Access Port (TAP)
 - Address Trace mode reflects internal Program RAM accesses at the external port

On-Chip Memories

 Program RAM, Instruction Cache, X data RAM, and Y data RAM size is programmable.

Instruction Cache	Switch Mode	Program RAM Size	Instruction Cache Size	X Data RAM Size	Y Data RAM Size
disabled	disabled	20480×24 -bit	0	7168×24 -bit	7168 × 24-bit
enabled	disabled	19456×24 -bit	1024×24 -bit	7168×24 -bit	7168 × 24-bit
disabled	enabled	24576×24 -bit	0	5120×24 -bit	5120 × 24-bit
enabled	enabled	23552×24 -bit	1024×24 -bit	5120×24 -bit	5120 × 24-bit

• 192 x 24-bit bootstrap ROM

Off-Chip Memory Expansion

- Data memory expansion to two 256 K \times 24-bit word memory spaces (or up to two 4 M \times 24-bit word memory spaces by using the Address Attribute AA0-AA3 signals)
- Program memory expansion to one 256 K × 24-bit words memory space (or up to one 4 M × 24-bit word memory space by using the Address Attribute AA0–AA3 signals)
- External memory expansion port
- Chip Select Logic for glueless interface to SRAMs
- On-chip DRAM Controller for glueless interface to DRAMs

On-Chip Peripherals

- Enhanced DSP56000-like 8-bit parallel Host Interface (HI08) supports a
 variety of buses (e.g., ISA) and provides glueless connection to a number of
 industry standard microcomputers, microprocessors, and DSPs
- Two Enhanced Synchronous Serial Interfaces (ESSI0 and ESSI1), each with one receiver and three transmitters (allows six-channel home theater)
- Serial Communications Interface (SCI) with baud rate generator
- Triple timer module
- Up to thirty-four programmable General Purpose Input/Output (GPIO) pins, depending on which peripherals are enabled

Reduced Power Dissipation

- Very low power CMOS design
- Wait and Stop low power standby modes
- Fully-static logic, operation frequency down to 0 Hz (dc)
- Optimized power management circuitry (instruction-dependent, peripheral-dependent, and mode-dependent)

TARGET APPLICATIONS

The DSP56302A is intended for applications requiring a large amount of on-chip memory, such as wireless infrastructure applications. It is also intended as a RAM-based emulation part for low-cost ROM-based solutions

Product Documentation

PRODUCT DOCUMENTATION

The three documents listed in the following table are required for a complete description of the DSP56302A and are necessary to design properly with the part. Documentation is available from one of the following locations (see back cover for detailed information):

- A local Motorola distributor
- A Motorola semiconductor sales office
- A Motorola Literature Distribution Center
- The World Wide Web (WWW)

See the **Additional Support** section of the *DSP56300 Family Manual* for detailed information on the multiple support options available to you.

Table 1 DSP56303 Documentation

Name	Description	Order Number
DSP56300 Family Manual	Detailed description of the DSP56300 family processor core and instruction set	DSP56300FM/AD
DSP56302 User's Manual	Detailed functional description of the DSP56302 memory configuration, operation, and register programming	DSP56302UM/AD
DSP56302A Technical Data	DSP56302A features list and physical, electrical, timing, and package specifications	DSP56302A/D

SECTION SIGNAL/CONNECTION DESCRIPTIONS

SIGNAL GROUPINGS

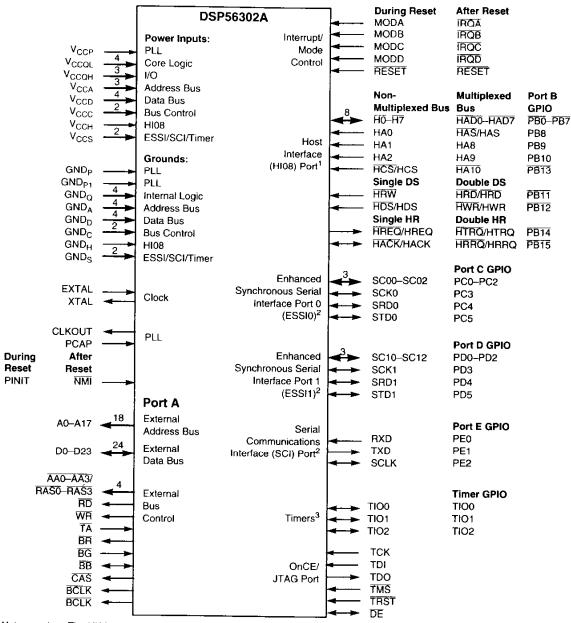

The input and output signals of the DSP56302A are organized into functional groups, as shown in Table 1-1 and as illustrated in Figure 1-1.

Table 1-1 DSP56302A Functional Signal Groupings

Functional Group	Number of Signals	Detailed Description	
Power (V _{CC})		20	Table 1-2
Ground (GND)		19	Table 1-3
Clock		2	Table 1-4
PLL		3	Table 1-5
Address Bus		18	Table 1-6
Data Bus	Port A ¹	24	Table 1-7
Bus Control		13	Table 1-8
Interrupt and Mode Control	5	Table 1-9	
Host Interface (HI08)	Port B ²	16	Table 1-11
Enhanced Synchronous Serial Interface (ESSI)	12	Table 1-12 and Table 1-13	
Serial Communication Interface (SCI)	3	Table 1-14	
Timer	3	Table 1-15	
OnCE/JTAG Port	6	Table 1-16	

and control signals.
Port B signals are the HI08 port signals multiplexed with the GPIO signals.
Port C and D signals are the two ESSI port signals multiplexed with the GPIO signals.
Port E signals are the SCI port signals multiplexed with the GPIO signals.

Figure 1-1 is a diagram of DSP56302A signals by functional group.

Notes:

- The HI08 port supports a non-multiplexed or a multiplexed bus, single or double Data Strobe (DS), and single or double Host Request (HR) configurations. Since each of these modes is configured independently, any combination of these modes is possible. These HI08 signals can also be configured alternately as GPIO signals (PB0-PB15). Signals with dual designations (e.g., HAS/HAS) have configurable polarity.
- The ESSI0, ESSI1, and SCI signals are multiplexed with the Port C GPIO signals (PC0–PC5), Port D GPIO signals (PD0–PD5), and Port E GPIO signals (PE0–PE2), respectively.

TIO0-TIO2 can be configured as GPIO signals.

AA0601

Figure 1-1 Signals Identified by Functional Group

POWER

Table 1-2 Power Inputs

Power Name	Description
V _{CCP}	PLL Power — V_{CCP} is V_{CC} dedicated for Phase Lock Loop (PLL) use. The voltage should be well-regulated and the input should be provided with an extremely low impedance path to the V_{CC} power rail. There is one V_{CCP} input.
V _{CCQL} (3)	Quiet Core (Low) Power — V_{CCQL} is an isolated power for the core processing logic. This input must be isolated externally from all other chip power inputs. The user must provide adequate external decoupling capacitors. There are three V_{CCQ} inputs.
V _{CCQH} (4)	Quiet External (High) Power — V_{CCQH} is a quiet power source for $1/O$ lines. This input must be tied externally to all other chip power inputs, <i>except</i> V_{CCQL} . The user must provide adequate decoupling capacitors. There are four V_{CCQH} inputs.
V _{CCA} (3)	Address Bus Power — V_{CCA} is an isolated power for sections of the address bus I/O drivers. This input must be tied externally to all other chip power inputs, <i>except</i> V_{CCQL} . The user must provide adequate external decoupling capacitors. There are four V_{CCA} inputs.
V _{CCD} (4)	Data Bus Power —V _{CCD} is an isolated power for sections of the data bus I/O drivers. This input must be tied externally to all other chip power inputs. The user must provide adequate external decoupling capacitors. There are four V _{CCD} inputs.
V _{CCC} (2)	Bus Control Power — V_{CCC} is an isolated power for the bus control I/O drivers. This input must be tied externally to all other chip power inputs, <i>except V_{CCQL}</i> . The user must provide adequate external decoupling capacitors. There are two V_{CCC} inputs.
V _{CCH}	Host Power — V_{CCH} is an isolated power for the HI08 I/O drivers. This input must be tied externally to all other chip power inputs, <i>except V_{CCQL}</i> . The user must provide adequate external decoupling capacitors. There is one V_{CCH} input.
V _{CCS} (2)	ESSI, SCI, and Timer Power — V_{CCS} is an isolated power for the ESSI, SCI, and timer I/O drivers. This input must be tied externally to all other chip power inputs, <i>except</i> V_{CCQL} . The user must provide adequate external decoupling capacitors. There are two V_{CCS} inputs.
other interr	gnations are package-dependent. Some packages connect all V_{CC} inputs except V_{CCP} to each nally. On those packages, all power input, except V_{CCP} , are labeled V_{CC} . The numbers of s indicated in this table are minimum values; the total V_{CC} connections are package- dependent.

GROUND

Table 1-3 Grounds

Ground Name	Description
GND _P	PLL Ground —GND _P is ground dedicated for PLL use. The connection should be provided with an extremely low-impedance path to ground. V_{CCP} should be bypassed to GND _P by a 0.47 μ F capacitor located as close as possible to the chip package. There is one GND _P connection.
GND _{P1}	PLL Ground 1 —GND _{P1} is ground dedicated for PLL use. The connection should be provided with an extremely low-impedance path to ground. There is one GND_{Pl} connection.
GND _Q (4)	Quiet Ground —GND $_Q$ is an isolated ground for the internal processing logic. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There are four GND $_Q$ connections.
GND _A (4)	Address Bus Ground — GND_A is an isolated ground for sections of the address bus I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There are four GND_A connections.
GND _D (4)	Data Bus Ground — GND_D is an isolated ground for sections of the data bus I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There are four GND_D connections.
GND _C (2)	Bus Control Ground — GND_C is an isolated ground for the bus control I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There are two GND_C connections.
GND _H	Host Ground —GND $_{\rm H}$ is an isolated ground for the HI08 I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There is one GND $_{\rm H}$ connection.
GND _S (2)	ESSI, SCI, and Timer Ground —GND _S is an isolated ground for the ESSI, SCI, and timer I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There are two GND _S connections.
GND _{P1} , to e labeled GNI	nations are package-dependent. Some packages connect all GND inputs, except GND, and each other internally. On those packages, all ground connections, except GND, and GND _{P1} , are D. The numbers of connections indicated in this table are minimum values; the total GND are package-dependent.

CLOCK

Table 1-4 Clock Signals

Signal Name	Туре	State During Reset	Signal Description
EXTAL	Input	Input	External Clock/Crystal Input—EXTAL interfaces the internal crystal oscillator input to an external crystal or an external clock.
XTAL	Output	Chip Driven	Crystal Output—XTAL connects the internal crystal oscillator output to an external crystal. If an external clock is used, leave XTAL unconnected.

PHASE LOCK LOOP (PLL)

 Table 1-5
 Phase Lock Loop Signals

Signal Name	Type	State During Reset	Signal Description
PCAP	Input	Input	PLL Capacitor —PCAP is an input connecting an off-chip capacitor to the PLL filter. Connect one capacitor terminal to PCAP and the other terminal to V _{CCP} .
			If the PLL is not used, PCAP may be tied to V_{CC} , GND, or left floating.
CLKOUT	Output	Chip Driven	Clock Output—CLKOUT provides an output clock synchronized to the internal core clock phase.
,			If the PLL is enabled and both the Multiplication and Division Factors equal one, then CLKOUT is also synchronized to EXTAL.
			If the PLL is disabled, the CLKOUT frequency is half the frequency of EXTAL.
PINIT	Input	Input	PLL Initial—During assertion of RESET, the value of PINIT is written into the PLL Enable (PEN) bit of the PLL Control (PCTL) register, determining whether the PLL is enabled or disabled.
NMI	Input		Non-Maskable Interrupt—After RESET deassertion and during normal instruction processing, this Schmitt-trigger input is the negative-edge-triggered Non-Maskable Interrupt (NMI) request internally synchronized to CLKOUT.

EXTERNAL MEMORY EXPANSION PORT (PORT A)

Note: When the DSP56302A enters a low-power standby mode (Stop or Wait), it releases bus mastership and tri-states the relevant Port A signals: A0–A17, D0–D23, AA0/RAS0–AA3/RAS3, RD, WR, BB, CAS, BCLK, BCLK.

EXTERNAL ADDRESS BUS

Table 1-6 External Address Bus Signals

Signal Name	Туре	State During Reset	Signal Description
A0-A17	Output	Tri-stated	Address Bus—When the DSP is the bus master, A0–A17 are active-high outputs that specify the address for external program and data memory accesses. Otherwise, the signals are tri-stated. To minimize power dissipation, A0–A17 do not change state when external memory spaces are not being accessed.

EXTERNAL DATA BUS

Table 1-7 External Data Bus Signals

Signal Name	Type	State During Reset	Signal Description
D0-D23	Input/ Output	Tri-stated	Data Bus—When the DSP is the bus master, D0–D23 are active-high, bidirectional input/outputs that provide the bidirectional data bus for external program and data memory accesses. Otherwise, D0–D23 are tri-stated.

EXTERNAL BUS CONTROL

Table 1-8 External Bus Control Signals

Signal Name	Type	State During Reset	Signal Description		
AA0-AA3	Output	Tri-stated	Address Attribute—When defined as AA, these signals can be used as chip selects or additional address lines.		
RASÕ-RAS3	Output		Row Address Strobe—When defined as RAS, these signals can be used as RAS for Dynamic Random Access Memory (DRAM) interface. These signals are tri-statable outputs with programmable polarity.		
RD	Output	Tri-stated	Read Enable —When the DSP is the bus master, \overline{RD} is an active-low output that is asserted to read external memory on the data bus (D0–D23). Otherwise, \overline{RD} is tri-stated.		

Table 1-8 External Bus Control Signals (Continued)

Signal Name	Туре	State During Reset	Signal Description
WR	Output	Tri-stated	Write Enable —When the DSP is the bus master, \overline{WR} is an active-low output that is asserted to write external memory on the data bus (D0–D23). Otherwise, the signals are tri-stated.
TA	Input	Ignored Input	Transfer Acknowledge—If the DSP56302A is the bus master and there is no external bus activity, or the DSP56302A is not the bus master, the TA input is ignored. The TA input is a Data Transfer Acknowledge (DTACK) function that can extend an external bus cycle indefinitely. Any number of wait states (1, 2,, infinity) may be added to the wait states inserted by the BCR by keeping TA deasserted. In typical operation, TA is deasserted at the start of a bus cycle, is asserted to enable completion of the bus cycle, and is deasserted before the next bus cycle. The current bus cycle completes one clock period after TA is asserted synchronous to CLKOUT. The number of wait states is determined by the TA input or by the Bus Control Register (BCR), whichever is longer. The BCR can be used to set the minimum number of wait states in external bus cycles. In order to use the TA functionality, the BCR must be programmed to at least one wait state. A zero wait state access can not be extended by TA deassertion, otherwise improper operation may result. TA can operate synchronously or asynchronously depending on the setting of the TAS bit in the Operating Mode Register (OMR). TA functionality may not be used while performing DRAM type accesses, otherwise improper operation may result.
BR	Output	Output (deasserted)	Bus Request— \overline{BR} is an active-low output, never tri-stated. \overline{BR} is asserted when the DSP requests bus mastership. \overline{BR} is deasserted when the DSP no longer needs the bus. \overline{BR} may be asserted or deasserted independent of whether the DSP56302A is a bus master or a bus slave. Bus "parking" allows \overline{BR} to be deasserted even though the DSP56302A is the bus master (see the description of bus "parking" in the \overline{BB} signal description). The Bus Request Hole (BRH) bit in the BCR allows \overline{BR} to be asserted under software control even though the DSP does not need the bus. \overline{BR} is typically sent to an external bus arbitrator that controls the priority, parking and tenure of each master on the same external bus. \overline{BR} is only affected by DSP requests for the external bus, never for the internal bus. During hardware reset, \overline{BR} is deasserted and the arbitration is reset to the Bus Slave state.

External Memory Expansion Port (Port A)

 Table 1-8
 External Bus Control Signals (Continued)

Signal Name	Type	State During Reset	Signal Description
BG	Input	Ignored Input	Bus Grant— \overline{BG} is an active-low input. \overline{BG} must be asserted/deasserted synchronous to CLKOUT for proper operation. \overline{BG} is asserted by an external bus arbitration circuit when the DSP56302A becomes the next bus master. When \overline{BG} is asserted, the DSP56302A must wait until \overline{BB} is deasserted before taking bus mastership. When \overline{BG} is deasserted, bus mastership is typically given up at the end of the current bus cycle. This may occur in the middle of an instruction that requires more than one external bus cycle for execution.
BB	Input/ Output	Input	Bus Busy— \overline{BB} is a bidirectional active-low input/output and must be asserted and deasserted synchronous to CLKOUT. \overline{BB} indicates that the bus is active. Only after \overline{BB} is deasserted can the pending bus master become the bus master (and then assert the signal again). The bus master may keep \overline{BB} asserted after ceasing bus activity regardless of whether \overline{BR} is asserted or deasserted. This is called "bus parking" and allows the current bus master to reuse the bus without re-arbitration until another device requires the bus. The deassertion of \overline{BB} is done by an "active pull-up" method (i.e., \overline{BB} is driven high and then released and held high by an external pull-up resistor).
CAS	Output	Tri-stated	BB requires an external pull-up resistor. Column Address Strobe—When the DSP is the bus master, CAS is an active-low output used by DRAM to strobe the column address. Otherwise, if the Bus Mastership Enable (BME) bit in the DRAM Control Register is cleared, the signal is tri-stated.
BCLK	Output	Tri-stated	Bus Clock—When the DSP is the bus master, BCLK is an active-high output. BCLK is active as a sampling signal when the program Address Tracing mode is enabled (by setting the ATE bit in the OMR). When BCLK is active and synchronized to CLKOUT by the internal PLL, BCLK precedes CLKOUT by one-fourth of a clock cycle. The BCLK rising edge may be used to sample the internal Program Memory access on the A0–A23 address lines.
BCLK	Output	Tri-stated	Bus Clock Not—When the DSP is the bus master, BCLK is an active-low output and is the inverse of the BCLK signal. Otherwise, the signal is tri-stated.

INTERRUPT AND MODE CONTROL

The interrupt and mode control signals select the chip's operating mode as it comes out of hardware reset. After RESET is deasserted, these inputs are hardware interrupt request lines.

Table 1-9 Interrupt and Mode Control

Signal Name	Type	State During Reset	Signal Description
RESET	Input	Input	Reset—RESET is an active-low, Schmitt-trigger input. Deassertion of RESET is internally synchronized to the clock out (CLKOUT). When asserted, the chip is placed in the Reset state and the internal phase generator is reset. The Schmitt-trigger input allows a slowly rising input (such as a capacitor charging) to reset the chip reliably. If RESET is deasserted synchronous to CLKOUT, exact start-up timing is guaranteed, allowing multiple processors to start synchronously and operate together in "lock-step." When the RESET signal is deasserted, the initial chip operating mode is latched from the MODA, MODB, MODC, and MODD inputs. The RESET signal must be asserted after power up.
MODA	Input	Input	Mode Select A—MODA is an active-low Schmitt-trigger input, internally synchronized to CLKOUT. MODA, MODB, MODC, and MODD select one of sixteen initial chip operating modes, latched into the OMR when the RESET signal is deasserted.
ĪRQĀ	Input		External Interrupt Request A—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. If \overline{IRQA} is asserted synchronous to CLKOUT, multiple processors can be re-synchronized using the WAIT instruction and asserting \overline{IRQA} to exit the Wait state. If the processor is in the Stop standby state and \overline{IRQA} is asserted, the processor will exit the Stop state.

Table 1-9 Interrupt and Mode Control (Continued)

Signal Name	Type	State During Reset	Signal Description
MODB	Input	Input	Mode Select B—MODB is an active-low Schmitt-trigger input, internally synchronized to CLKOUT. MODA, MODB, MODC, and MODD select one of sixteen initial chip operating modes, latched into the OMR when the RESET signal is deasserted.
ĪRQB	Input		External Interrupt Request B—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. If \overline{IRQB} is asserted synchronous to CLKOUT, multiple processors can be re-synchronized using the WAIT instruction and asserting \overline{IRQB} to exit the Wait state. If the processor is in the Stop standby state and \overline{IRQB} is asserted, the processor will exit the Stop state.
MODC	Input	Input	Mode Select C—MODC is an active-low Schmitt-trigger input, internally synchronized to CLKOUT. MODA, MODB, MODC, and MODD select one of sixteen initial chip operating modes, latched into the OMR when the RESET signal is deasserted.
ĪRQC	Input		External Interrupt Request C—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. If IRQC is asserted synchronous to CLKOUT, multiple processors can be re-synchronized using the WAIT instruction and asserting IRQC to exit the Wait state. If the processor is in the Stop standby state and IRQC is asserted, the processor will exit the Stop state.
MODD	Input	Input	Mode Select D—MODD is an active-low Schmitt-trigger input, internally synchronized to CLKOUT. MODA, MODB, MODC, and MODD select one of sixteen initial chip operating modes, latched into the OMR when the RESET signal is deasserted.
ĪRQD	Input		External Interrupt Request D—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. If \overline{IRQD} is asserted synchronous to CLKOUT, multiple processors can be re-synchronized using the WAIT instruction and asserting \overline{IRQD} to exit the Wait state. If the processor is in the Stop standby state and \overline{IRQD} is asserted, the processor will exit the Stop state.

HOST INTERFACE (HI08)

The HI08 provides a fast parallel data to 8-bit port, which may be connected directly to the host bus.

The HI08 supports a variety of standard buses, and can be directly connected to a number of industry standard microcomputers, microprocessors, DSPs, and DMA hardware.

Host Port Usage Considerations

Careful synchronization is required when reading multiple-bit registers that are written by another asynchronous system. This is a common problem when two asynchronous systems are connected (as they are in the Host port). The considerations for proper operation are discussed in the following table:

Table 1-10 Host Port Usage Considerations

Action	Description		
Asynchronous read of receive byte registers	When reading the receive byte registers, Receive register High (RXH), Receive register Middle (RXM), or Receive register Low (RXL), the host interface programmer should use interrupts or poll the Receive register Data Full (RXDF) flag which indicates that data is available. This assures that the data in the receive byte registers will be valid.		
Asynchronous write to transmit byte registers	The host interface programmer should not write to the transmit byte registers, Transmit register High (TXH), Transmit register Middle (TXM), or Transmit register Low (TXL), unless the Transmit register Data Empty (TXDE) bit is set indicating that the transmit byte registers are empty. This guarantees that the transmit byte registers will transfer valid data to the Host Receive (HRX) register.		
Asynchronous write to host vector	The host interface programmer should change the Host Vector (HV) register only when the Host Command bit (HC) is clear. This will guarantee that the DSP interrupt control logic will receive a stable vector.		

Host Interface (HI08)

Host Port Configuration

The functions of the signals associated with the HI08 vary according to the programmed configuration of the interface as determined by the 16 bits in the HI08 Port Control Register (HPCR). Refer to the *DSP56302AUser's Manual* for detailed descriptions of this and the other configuration registers used with the HI08.

Table 1-11 Host Interface

Signal Name	Туре	State During Reset	Signal Description
H0–H7	Input/ Output	Tri-stated	Host Data—When the HI08 is programmed to interface a non-multiplexed host bus and the HI function is selected, these signals are lines 0-7 of the Data bidirectional, tri-state bus.
HAD0-HAD7	Input/ Output		Host Address—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, these signals are lines 0–7 of the Address/Data bidirectional, multiplexed, tri-state bus.
РВ0-РВ7	Input or Output		Port B 0–7—When the HI08 is configured as GPIO through the HPCR, these signals are individually programmed as inputs or outputs through the HI08 Data Direction Register (HDDR).
НА0	Input	Input	Host Address Input 0—When the HI08 is programmed to interface a non-multiplexed host bus and the HI function is selected, this signal is line 0 of the Host Address input bus.
HAS/HAS	Input		Host Address Strobe—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is the Host Address Strobe (HAS) Schmitt-trigger input. The polarity of the address strobe is programmable but is configured active-low (HAS) following reset.
РВ8	Input or Output		Port B 8—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.

Table 1-11 Host Interface (Continued)

Signal Name	Type	State During Reset	Signal Description
HA1	Input	Input	Host Address Input 1—When the HI08 is programmed to interface a non-multiplexed host bus and the HI function is selected, this signal is line 1 of the Host Address (HA1) input bus.
HA8	Input		Host Address 8—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is line 8 of the Host Address (HA8) input bus.
PB9	Input or Output		Port B 9—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.
HA2	Input	Input	Host Address Input 2—When the HI08 is programmed to interface a non-multiplexed host bus and the HI function is selected, this signal is line 2 of the Host Address (HA2) input bus.
НА9	Input		Host Address 9—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is line 9 of the Host Address (HA9) input bus.
PB10	Input or Output		Port B 10 —When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.
HRW	Input	Input	Host Read/Write—When HI08 is programmed to interface a single-data-strobe host bus and the HI function is selected, this signal is the Host Read/Write (HRW) input.
HRD/HRD	Input		Host Read Data—When HI08 is programmed to interface a double-data-strobe host bus and the HI function is selected, this signal is the Host Read Data strobe (HRD) Schmitt-trigger input. The polarity of the data strobe is programmable, but is configured as active-low (HRD) after reset.
PB11	Input or Output		Port B 11—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.

Table 1-11 Host Interface (Continued)

Signal Name	Туре	State During Reset	Signal Description
HDS/HDS	Input	Input	Host Data Strobe—When HI08 is programmed to interface a single-data-strobe host bus and the HI function is selected, this signal is the Host Data Strobe (HDS) Schmitt-trigger input. The polarity of the data strobe is programmable, but is configured as active-low (HDS) following reset.
HWR/HWR	Input		Host Write Data—When HI08 is programmed to interface a double-data-strobe host bus and the HI function is selected, this signal is the Host Write Data Strobe (HWR) Schmitt-trigger input. The polarity of the data strobe is programmable, but is configured as active-low (HWR) following reset.
PB12	Input or Output		Port B 12—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.
HCS	Input	Input	Host Chip Select—When HI08 is programmed to interface a non-multiplexed host bus and the HI function is selected, this signal is the Host Chip Select (HCS) input. The polarity of the chip select is programmable, but is configured active-low (HCS) after reset.
HA10	Input		Host Address 10—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is line 10 of the Host Address (HA10) input bus.
PB13	Input or Output		Port B 13—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.

Table 1-11 Host Interface (Continued)

Signal Name	Туре	State During Reset	Signal Description
HREQ/HREQ	Output	Input	Host Request—When HI08 is programmed to interface a single host request host bus and the HI function is selected, this signal is the Host Request (HREQ) output. The polarity of the host request is programmable, but is configured as active-low (HREQ) following reset. The host request may be programmed as a driven or open-drain output.
HTRQ/HTRQ	Output		Transmit Host Request—When HI08 is programmed to interface a double host request host bus and the HI function is selected, this signal is the Transmit Host Request (HTRQ) output. The polarity of the host request is programmable, but is configured as active-low (HTRQ) following reset. The host request may be programmed as a driven or open-drain output.
PB14	Input or Output		Port B 14—When the I II08 is programmed to interface a multiplexed host bus and the signal is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.
HACK/HACK	Input	Input	Host Acknowledge—When HI08 is programmed to interface a single host request host bus and the HI function is selected, this signal is the Host Acknowledge (HACK) Schmitt-trigger input. The polarity of the host acknowledge is programmable, but is configured as active-low (HACK) after reset.
HRRQ/HRRQ	Output		Receive Host Request—When HI08 is programmed to interface a double host request host bus and the HI function is selected, this signal is the Receive Host Request (HRRQ) output. The polarity of the host request is programmable, but is configured as active-low (HRRQ) after reset. The host request may be programmed as a driven or open-drain output.
PB15	Input or Output		Port B 15 —When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR.

ENHANCED SYNCHRONOUS SERIAL INTERFACE 0 (ESSI0)

There are two synchronous serial interfaces (ESSI0 and ESSI1) that provide a full-duplex serial port for serial communication with a variety of serial devices, including one or more industry-standard codecs, other DSPs, microprocessors, and peripherals which implement the Motorola Serial Peripheral Interface (SPI).

 Table 1-12
 Enhanced Synchronous Serial Interface 0 (ESSI0)

Signal Name	Туре	State During Reset	Signal Description
SC00	Input or Output	Input	Serial Control 0—The function of SC00 is determined by the selection of either Synchronous or Asynchronous mode. For Asynchronous mode, this signal will be used for the receive clock I/O (Schmitttrigger input). For Synchronous mode, this signal is used either for Transmitter 1 output or for Serial I/O Flag 0.
PC0			Port C 0—The default configuration following reset is GPIO input PC0. When configured as PC0, signal direction is controlled through the Port Directions Register (PRR0). The signal can be configured as ESSI signal SC00 through the Port Control Register (PCR0).
SC01	Input/Output	Input	Serial Control 1—The function of this signal is determined by the selection of either Synchronous or Asynchronous mode. For Asynchronous mode, this signal is the receiver frame sync I/O. For Synchronous mode, this signal is used either for Transmitter 2 output or for Serial I/O Flag 1.
PC1	Input or Output		Port C 1—The default configuration following reset is GPIO input PC1. When configured as PC1, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SC01 through PCR0.

Enhanced Synchronous Serial Interface 0 (ESSI0)

 Table 1-12
 Enhanced Synchronous Serial Interface 0 (ESSI0) (Continued)

Signal Name	Type	State During Reset	Signal Description
SC02	Input/Output	Input	Serial Control Signal 2—SC02 is used for frame sync I/O. SC02 is the frame sync for both the transmitter and receiver in Synchronous mode, and for the transmitter only in Asynchronous mode. When configured as an output, this signal is the internally generated frame sync signal. When configured as an input, this signal receives an external frame sync signal for the transmitter (and the receiver in synchronous operation).
PC2	Input or Output		Port C 2 —The default configuration following reset is GPIO input PC2. When configured as PC2, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SC02 through PCR0.
SCK0	Input/Output	Input	Serial Clock—SCK0 is a bidirectional Schmitt-trigger input signal providing the serial bit rate clock for the ESSI. The SCK0 is a clock input or output used by both the transmitter and receiver in Synchronous modes, or by the transmitter in Asynchronous modes.
			Although an external serial clock can be independent of and asynchronous to the DSP system clock, it must exceed the minimum clock cycle time of 6T (i.e., the system clock frequency must be at least three times the external ESSI clock frequency). The ESSI needs at least three DSP phases inside each half of the serial clock.
PC3	Input or Output		Port C 3 —The default configuration following reset is GPIO input PC3. When configured as PC3, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SCK0 through PCR0.
SRD0	Input/Output	Input	Serial Receive Data—SRD0 receives serial data and transfers the data to the ESSI receive shift register. SRD0 is an input when data is being received.
PC4	Input or Output		Port C 4—The default configuration following reset is GPIO input PC4. When configured as PC4, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SRD0 through PCR0.

Enhanced Synchronous Serial Interface 0 (ESSI0)

 Table 1-12
 Enhanced Synchronous Serial Interface 0 (ESSI0) (Continued)

Signal Name	Туре	State During Reset	Signal Description
STD0	Input/Output	Input	Serial Transmit Data—STD0 is used for transmitting data from the serial transmit shift register. STD0 is an output when data is being transmitted.
PC5	Input or Output		Port C 5 —The default configuration following reset is GPIO input PC5. When configured as PC5, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal STD0 through PCR0.

ENHANCED SYNCHRONOUS SERIAL INTERFACE 1 (ESSI1)

 Table 1-13
 Enhanced Synchronous Serial Interface 1 (ESSI1)

Signal Name	Type	State During Reset	Signal Description
SC10	Input or Output	Input	Serial Control 0—The function of SC10 is determined by the selection of either Synchronous or Asynchronous mode. For Asynchronous mode, this signal will be used for the receive clock I/O (Schmitttrigger input). For Synchronous mode, this signal is used either for Transmitter 1 output or for Serial I/O Flag 0.
PD0	Input or Output		Port D 0 —The default configuration following reset is GPIO input PD0. When configured as PD0, signal direction is controlled through the Port Directions Register (PRR1). The signal can be configured as an ESSI signal SC10 through the Port Control Register (PCR1).
SC11	Input/Output	Input	Serial Control 1—The function of this signal is determined by the selection of either Synchronous or Asynchronous mode. For Asynchronous mode, this signal is the receiver frame sync I/O. For Synchronous mode, this signal is used either for Transmitter 2 output or for Serial I/O Flag 1.
PD1	Input or Output		Port D 1—The default configuration following reset is GPIO input PD1. When configured as PD1, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SC11 through PCR1.
SC12	Input/Output	Input	Serial Control Signal 2—SC12 is used for frame sync I/O. SC12 is the frame sync for both the transmitter and receiver in Synchronous mode, and for the transmitter only in Asynchronous mode. When configured as an output, this signal is the internally generated frame sync signal. When configured as an input, this signal receives an external frame sync signal for the transmitter (and the receiver in Synchronous operation).
PD2	Input or Output		Port D 2—The default configuration following reset is GPIO input PD2. When configured as PD2, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SC12 through PCR1.

Enhanced Synchronous Serial Interface 1 (ESSI1)

Table 1-13 Enhanced Synchronous Serial Interface 1 (ESSI1) (Continued)

Signal Name	Туре	State During Reset	Signal Description
SCK1	Input/Output	Input	Serial Clock—SCK1 is a bidirectional Schmitt-trigger input signal providing the serial bit rate clock for the ESSI. The SCK1 is a clock input or output used by both the transmitter and receiver in Synchronous modes, or by the transmitter in Asynchronous modes.
			Although an external serial clock can be independent of and asynchronous to the DSP system clock, it must exceed the minimum clock cycle time of 6T (i.e., the system clock frequency must be at least three times the external ESSI clock frequency). The ESSI needs at least three DSP phases inside each half of the serial clock.
PD3	Input or Output		Port D 3—The default configuration following reset is GPIO input PD3. When configured as PD3, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SCK1 through PCR1.
SRD1	Input/Output	Input	Serial Receive Data—SRD1 receives serial data and transfers the data to the ESSI receive shift register. SRD1 is an input when data is being received.
PD4	Input or Output		Port D 4—The default configuration following reset is GPIO input PD4. When configured as PD4, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SRD1 through PCR1.
STD1	Input/Output	Input	Serial Transmit Data—STD1 is used for transmitting data from the serial transmit shift register. STD1 is an output when data is being transmitted.
PD5	Input or Output		Port D 5—The default configuration following reset is GPIO input PD5. When configured as PD5, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal STD1 through PCR1.

SERIAL COMMUNICATION INTERFACE (SCI)

The Serial Communication interface (SCI) provides a full duplex port for serial communication to other DSPs, microprocessors, or peripherals such as modems.

Table 1-14 Serial Communication Interface (SCI)

Signal Name	Type	State During Reset	Signal Description
RXD	Input	Input	Serial Receive Data—This input receives byte oriented serial data and transfers it to the SCI receive shift register.
PE0	Input or Output		Port E 0—The default configuration following reset is GPIO input PE0. When configured as PE0, signal direction is controlled through the SCI Port Directions Register (PRR). The signal can be configured as an SCI signal RXD through the SCI Port Control Register (PCR).
TXD	Output	Input	Serial Transmit Data—This signal transmits data from SCI transmit data register.
PE1	Input or Output		Port E 1—The default configuration following reset is GPIO input PE1. When configured as PE1, signal direction is controlled through the SCI PRR. The signal can be configured as an SCI signal TXD through the SCI PCR.
SCLK	Input/Output	Input	Serial Clock —This is the bidirectional Schmitt-trigger input signal providing the input or output clock used by the transmitter and/or the receiver.
PE2	Input or Output		Port E 2—The default configuration following reset is GPIO input PE2. When configured as PE2, signal direction is controlled through the SCI PRR. The signal can be configured as an SCI signal SCLK through the SCI PCR.

TimerS

TIMERS

Three identical and independent timers are implemented in the DSP56302A. Each timer can use internal or external clocking, and can interrupt the DSP56302A after a specified number of events (clocks), or can signal an external device after counting a specific number of internal events.

Table 1-15 Triple Timer Signals

	1		
Signal Name	Туре	State During Reset	Signal Description
TIO0	Input or Output	Input	Timer 0 Schmitt-Trigger Input/Output—When Timer 0 functions as an external event counter or in Measurement mode, TIO0 is used as input. When Timer 0 functions in Watchdog, Timer, or Pulse Modulation mode, TIO0 is used as output. The default mode after reset is GPIO input. This can be changed to output or configured as a Timer Input/Output through the Timer 0 Control/Status Register (TCSR0).
TIO1	Input or Output	Input	Timer 1 Schmitt-Trigger Input/Output—When Timer 1 functions as an external event counter or in Measurement mode, TIO1 is used as input. When Timer 1 functions in Watchdog, Timer, or Pulse Modulation mode, TIO1 is used as output. The default mode after reset is GPIO input. This can be changed to output or configured as a Timer Input/Output through the Timer 1 Control/Status Register (TCSR1).
TIO2	Input or Output	Input	Timer 2 Schmitt-Trigger Input/Output—When Timer 2 functions as an external event counter or in Measurement mode, TIO2 is used as input. When Timer 2 functions in Watchdog, Timer, or Pulse Modulation mode, TIO2 is used as output. The default mode after reset is GPIO input. This can be changed to output or configured as a Timer Input/Output through the Timer 2 Control/Status Register (TCSR2).

OnCE/JTAG INTERFACE

Table 1-16 OnCE/JTAG Interface

Signal Name	Туре	State During Reset	Signal Description
TCK	Input	Input	Test Clock —TCK is a test clock input signal used to synchronize the JTAG test logic.
TDI	Input	Input	Test Data Input—TDI is a test data serial input signal used for test instructions and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TDO	Output	Tri-stated	Test Data Output—TDO is a test data serial output signal used for test instructions and data. TDO is tristatable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TMS	Input	Input	Test Mode Select—TMS is an input signal used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TRST	Input	Input	Test Reset—TRST is an active-low Schmitt-trigger input signal used to asynchronously initialize the test controller. TRST has an internal pull-up resistor. TRST must be asserted after power up.

OnCE/JTAG Interface

Table 1-16 OnCE/JTAG Interface (Continued)

Signal Name	Туре	State During Reset	Signal Description
DE	Input/Output	Input	Debug Event—DE is an open-drain, bidirectional, active-low signal providing, as an input, a means of entering the Debug mode of operation from an external command controller, and, as an output, a means of acknowledging that the chip has entered the Debug mode. This signal, when asserted as an input, causes the DSP56300 core to finish the current instruction being executed, save the instruction pipeline information, enter the Debug mode, and wait for commands to be entered from the debug serial input line. This signal is asserted as an output for three clock cycles when the chip enters the Debug mode as a result of a debug request or as a result of meeting a breakpoint condition. The DE has an internal pull-up resistor.
			This is not a standard part of the JTAG Test Access Port (TAP) Controller. The signal connects directly to the OnCE module to initiate Debug mode directly or to provide a direct external indication that the chip has entered the Debug mode. All other interface with the OnCE module must occur through the JTAG port.

SECTION 2 SPECIFICATIONS

INTRODUCTION

The DSP56302A is fabricated in high density CMOS with Transistor-Transistor Logic (TTL) compatible inputs and outputs. The DSP56302A specifications are preliminary and are from design simulations, and may not be fully tested or guaranteed at this early stage of the product life cycle. Finalized specifications will be published after full characterization and device qualifications are complete.

MAXIMUM RATINGS

CAUTION

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, normal precautions should be taken to avoid exceeding maximum voltage ratings. Reliability is enhanced if unused inputs are tied to an appropriate logic voltage level (e.g., either GND or V_{CC}).

Note: In the calculation of timing requirements, adding a maximum value of one specification to a minimum value of another specification does not yield a reasonable sum. A maximum specification is calculated using a worst case variation of process parameter values in one direction. The minimum specification is calculated using the worst case for the same parameters in the opposite direction. Therefore, a "maximum" value for a specification will

never occur in the same device that has a "minimum" value for another specification; adding a maximum to a minimum represents a condition that can never exist.

Table 2-1 Maximum Ratings

Rating ¹	Symbol	Value ^{1, 2}	Unit
Supply Voltage	V _{CC}	-0.3 to +4.0	V
All input voltages	V _{IN}	GND $- 0.3$ to $V_{CC} + 0.3$	V
Current drain per pin excluding $ m V_{CC}$ and GND	I	10	mA
Operating temperature range	T _J	-40 to +100	°C
Storage temperature	T _{STG}	−55 to +150	°C

- Notes: 1. GND = 0 V, $V_{CC} = 3.3 \text{ V} \pm 0.3 \text{ V}$, $T_1 = -40^{\circ}\text{C}$ to +100°C, CL = 50 pF
 - 2. Absolute maximum ratings are stress ratings only, and functional operation at the maximum is not guaranteed. Stress beyond the maximum rating may affect device reliability or cause permanent damage to the device.

THERMAL CHARACTERISTICS

Table 2-2 Thermal Characteristics

Characteristic	Symbol	TQFP Value	PBGA ³ Value	PBGA ⁴ Value	Unit
Junction-to-ambient thermal resistance ¹	$R_{\theta JA}$ or θ_{JA}	49.3	49.4	28.5	°C/W
Junction-to-case thermal resistance ²	$R_{\theta JC}$ or θ_{JC}	8.2	12.0	_	°C/W
Thermal characterization parameter	Ψ_{JT}	5.5	2.0		°C/W

- Notes: 1. Junction-to-ambient thermal resistance is based on measurements on a horizontal single-sided Printed Circuit Board per SEMI G38-87 in natural convection. (SEMI is Semiconductor Equipment and Materials International, 805 East Middlefield Rd., Mountain View, CA 94043, (415) 964-5111) Measurements were done with parts mounted on thermal test boards conforming to specification
 - 2. Junction-to-case thermal resistance is based on measurements using a cold plate per SEMI G30-88, with the exception that the cold plate temperature is used for the case temperature.
 - 3. These are simulated values; testing is not complete. See Note 1 for test board conditions.
 - 4. These are simulated values; testing is not complete. The test board has two, 2-ounce signal layers and two 1-ounce solid ground planes internal to the test board.

DC ELECTRICAL CHARACTERISTICS

 Table 2-3
 DC Electrical Characteristics¹

Characteristics	Symbol	Min	Тур	Max	Unit

	8.	In order to obtain these results, all input (i.e., not allowed to float).		re not disconn	ected at Stop mo	ode, must be ter	minated				

AC ELECTRICAL CHARACTERISTICS

The timing waveforms shown in the ac electrical characteristics section are tested with a V_{IL} maximum of 0.3 V and a V_{IH} minimum of 2.4 V for all pins except EXTAL, which is tested using the input levels shown in **Note 6** of the previous table. AC timing specifications, which are referenced to a device input signal, are measured in production with respect to the 50% point of the respective input signal's transition. DSP56302A output levels are measured with the production test machine V_{OL} and V_{OH} reference levels set at 0.8 V and 2.0 V, respectively.

INTERNAL CLOCKS

Table 2-4 Internal Clocks, CLKOUT

Characteristics	Cumb al	Expression ^{1, 2}

Multiplication Factor PDF = Predivision Factor

= internal clock cycle

 T_C = internal clock cycle
 See the PLL and Clock Generation section in the *DSP56300 Family Manual* for a detailed discussion of the PLL.

EXTERNAL CLOCK OPERATION

The DSP56302A system clock may be derived from the on-chip crystal oscillator, as shown in Figure 1 on the cover page, or it may be externally supplied. An externally supplied square wave voltage source should be connected to EXTAL (see Figure 2-2), leaving XTAL physically not connected to the board or socket.

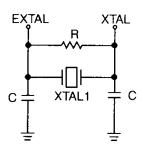

Fundamental Frequency Fork Crystal Oscillator

Suggested Component Values:

 $f_{OSC} = 32.768 \text{ kHz}$ $R1 = 3.9 M\Omega \pm 10\%$ С $= 22 pF \pm 20\%$ = $200 \text{ k}\Omega \pm 10\%$

Calculations were done for a 32.768 kHz crystal with the following parameters:

- a load capacitance (C_L) of 12.5 pF, a shunt capacitance (C_0) of 1.8 pF,
- a series resistance of $40 \text{ k}\Omega$, and
- a drive level of 1 μ W.

Fundamental Frequency Crystal Oscillator

Suggested Component Values:

f_{OSC} - 4 MHz f_{OSC} = 20 MHz $680 \text{ k}\Omega \pm 10\%$ R = $680 \text{ k}\Omega \pm 10\%$ 56 pF ± 20% C = 22 pF \pm 20%

Calculations were done for a 4/20 MHz crystal with the following parameters:

- a C₁ of 30/20 pF,
- a C_0 of 7/6 pF,
- a series resistance of 100/20 Ω , and
- a drive level of 2 mW.

	With PLL enabled		15.15 ns	8.53 μs	12.50 ns	8.53 μs	10.00 ns	8.53 μs

Notes:

- 1. Measured at 50% of the input transition
- 2. The maximum value for PLL enabled is given for minimum V_{CO} and maximum MF.
- 3. Periodically sampled and not 100% tested
- 4. The maximum value for PLL enabled is given for minimum V_{CO} and maximum DF.
- 5. The skew is not guaranteed for any other MF value.
- 6. The indicated duty cycle is for the specified maximum frequency for which a part is rated. The minimum clock high or low time required for correction operation, however, remains the same at lower operating frequencies; therefore, when a lower clock frequency is used, the signal symmetry may vary from the specified duty cycle as long as the minimum high time and low time requirements are met.

PHASE LOCK LOOP (PLL) CHARACTERISTICS

Table 2-6 PLL Characteristics

	66 N	ИНz	80 N	МНz	100	MHz	
Characteristics	Min	Max	Min	Max	Min	Max	Unit
V _{CO} frequency when PLL enabled (MF × E _f × 2/PDF)	30	132	30	160	30	200	MHz
PLL external capacitor (PCAP pin to V _{CCP}) (C _{PCAP} ¹⁾							
• @ MF ≤ 4	(MF×425) – 125	(MF×590) – 175	(MF×425) – 125	(MF×590) – 175	(MF×425) – 125	(MF×590) – 175	рF
• @ MF > 4	MF × 520	MF×920	MF × 520	MF × 920	MF × 520	MF × 920	рF

Note: C_{PCAP} is the value of the PLL capacitor (connected between the PCAP pin and V_{CCP}). The recommended value in pF for C_{PCAP} can be computed from one of the following equations: $(680 \times MF) - 120$, for MF < 3, or

 $1100 \times MF$, for MF ≥ 3.

- Notes: 1. When using fast interrupts and IRQA, IRQB, IRQC, and IRQD are defined as level-sensitive, timings 19 through 21 apply to prevent multiple interrupt service. To avoid these timing restrictions, the deasserted Edge-triggered mode is recommended when using fast interrupts. Long interrupts are recommended when using Level-sensitive mode.
 - This timing depends on several settings:

For PLL disable, using internal oscillator (PLL Control Register (PCTL) Bit 16 = 0) and oscillator disabled during Stop (PCTL Bit 17 = 0), a stabilization delay is required to assure the oscillator is stable before executing programs. In that case, resetting the Stop delay (OMR Bit 6 = 0) will provide the proper delay. While it is possible to set OMR Bit 6 = 1, it is not recommended and these specifications do not guarantee timings for that case.

For PLL disable, using internal oscillator (PCTL Bit 16 = 0) and oscillator enabled during Stop (PCTL Bit 17=1), no stabilization delay is required and recovery time will be minimal (OMR Bit 6 setting is ignored).

For PLL disable, using external clock (PCTL Bit 16 = 1), no stabilization delay is required and recovery time will be defined by the PCTL Bit 17 and OMR Bit 6 settings.

For PLL enable, if PCTL Bit 17 is 0, the PLL is shutdown during Stop. Recovering from Stop requires the PLL to get locked. The PLL lock procedure duration, PLL Lock Cycles (PLC), may be in the range of 0 to 1000 cycles. This procedure occurs in parallel with the stop delay counter, and stop recovery will end when the last of these two events occurs. The stop delay counter completes count or PLL lock procedure completion.

PLC value for PLL disable is 0.

The maximum value for ET_C is 4096 (maximum MF) divided by the desired internal frequency (i.e., for 66 MHz it is 4096/66 MHz = $62 \mu s$). During the stabilization period, T_C , T_{H_s} and T_L will not be constant, and their width may vary, so timing may vary as well.

Periodically sampled and not 100% tested

Table 2-7 Reset, Stop, Mode Select, and Interrupt Timing⁶ (Continued)

No.	Characteristics	Expression	66 1	66 MHz		80 MHz		100 MHz	
			Min	Max	Min	Max	Min	Max	Unit

4. For an external clock generator, $\overline{\text{RESET}}$ duration is measured during the time in which $\overline{\text{RESET}}$ is asserted, V_{CC} is valid, and the EXTAL input is active and valid.

For internal oscillator, \overline{RESET} duration is measured during the time in which \overline{RESET} is asserted and V_{CC} is valid. The specified timing reflects the crystal oscillator stabilization time after power-up. This number is affected both by the specifications of the crystal and other components connected to the oscillator and reflects worst case conditions.

When the V_{CC} is valid, but the other "required \overline{RESET} duration" conditions (as specified above) have not been yet met, the device circuitry will be in an uninitialized state that can result in significant power consumption and heat-up. Designs should minimize this state to the shortest possible duration.

- 5. If PLL does not lose lock
- 6. $V_{CC} = 3.3 \text{ V} \pm 0.3 \text{ V}$; $T_{I} = -40^{\circ}\text{C}$ to $+100^{\circ}\text{C}$, $C_{L} = 50 \text{ pF}$
- 7. WS = number of wait states (measured in clock cycles, number of T_C)
- 8. Use expression to compute maximum value.

Notes: 1. WS is the number of wait states specified in the BCR. 2. $V_{CC} = 3.3 \text{ V} \pm 0.3 \text{ V}$; $T_J = -40^{\circ}\text{C}$ to $+100^{\circ}\text{C}$, $C_L = 50 \text{ pF}$

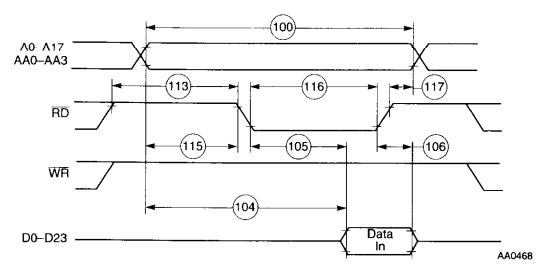

Figure 2-12 SRAM Read Access

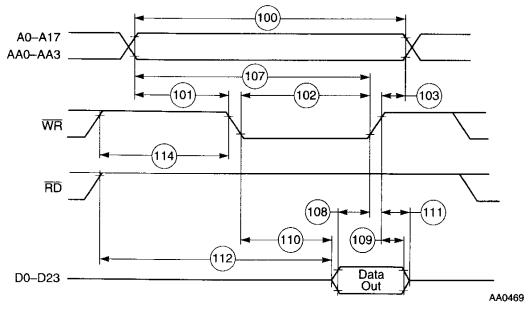

Figure 2-13 SRAM Write Access

DRAM Timing

The selection guides provided in **Figure 2-14** and **Figure 2-17** on page 2-37 should be used for primary selection only. Final selection should be based on the timing provided in the following tables. As an example, the selection guide suggests that 4 wait states must be used for 100 MHz operation when using Page Mode DRAM. However, by using the information in the appropriate table, a designer may choose to evaluate whether fewer wait states might be used by determining which timing prevents operation at 100 MHz, running the chip at a slightly lower frequency (e.g., 95 MHz), using faster DRAM (if it becomes available), and control factors such as capacitive and resistive load to improve overall system performance.

- Notes: 1. The number of wait states for Page mode access is specified in the DCR.
 - The refresh period is specified in the DCR.
 - All the timings are calculated for the worst case. Some of the timings are better for specific cases (e.g., t_{PC} equals $2 \times T_C$ for read-after-read or write-after-write sequences).
 - 4. BRW[1:0] (DRAM control register bits) defines the number of wait states that should be inserted in each DRAM out-of-page access.
 - RD deassertion will always occur after CAS deassertion; therefore, the restricted timing is tops and not
 - Reduced DSP clock speed allows use of Page Mode DRAM with one wait state (see Figure 2-14).

- Notes: 1. The number of wait states for Page mode access is specified in the DCR.
 - 2. The refresh period is specified in the DCR.

 - The asynchronous delays specified in the expressions are valid for DSP56302A.
 All the timings are calculated for the worst case. Some of the timings are better for specific cases (e.g., t_{PC} equals $3 \times T_{C}$ for read-after-read or write-after-write sequences).
 - 5. BRW[1:0] (DRAM control register bits) defines the number of wait states that should be inserted in each DRAM out-of-page access.
 - 6. RD deassertion will always occur after CAS deassertion; therefore, the restricted timing is t_{OFF} and not

Notes:

- 1. The number of wait states for out-of-page access is specified in the DCR.
- 2. The refresh period is specified in the DCR.
- 3. RD deassertion will always occur after CAS deassertion; therefore, the restricted timing is top: and not top.
- Reduced DSP clock speed allows use of DRAM out-of-page access with four wait states (see Figure 2-17).

- Notes: 1. See Host Port Usage Considerations on page 1-11.
 - In the timing diagrams below, the controls pins are drawn as active low. The pin polarity is
 - 3. This timing is applicable only if two consecutive reads from one of these registers are executed.
 - 4. The data strobe is Host Read (HRD) or Host Write (HWR) in the Dual Data Strobe mode and Host Data Strobe (HDS) in the Single Data Strobe mode.
 - 5. The read data strobe is HRD in the Dual Data Strobe mode and HDS in the Single Data Strobe mode.
 - The write data strobe is HWR in the Dual Data Strobe mode and HDS in the Single Data Strobe mode.
 - 7. The host request is HREQ in the Single Host Request mode and HRRQ and HTRQ in the Double Host Request mode.
 - The "Last Data Register" is the register at address \$7, which is the last location to be read or written in data transfers. This is RXL/TXL in the Little Endian mode (HBE = 0), or RXH/TXH in the Big Endian mode (HBE = 1).
 - In this calculation, the host request signal is pulled up by a 4.7 $k\Omega$ resistor in the Open-drain mode.
 - 10. $V_{CC} = 3.3 \text{ V} \pm 0.3 \text{ V}$; $T_I = -40 ^{\circ}\text{C}$ to $+100 ^{\circ}\text{C}$, $C_L = 50 \text{ pF}$
 - 11. This timing is applicable only if a read from the "Last Data Register" is followed by a read from the RXL, RXM, or RXH registers without first polling RXDF or HREQ bits, or waiting for the assertion of the HREQ signal.

- Notes: 1. For the internal clock, the external clock cycle is defined by Icyc and the ESSI control register. The word-relative frame sync signal waveform relative to the clock operates in the same manner as the bit-length frame sync signal waveform, but spreads from one serial clock before first bit clock (same as Bit Length Frame Sync signal), until the one before last bit clock of the first word in frame.
 - Periodically sampled and not 100% tested
 - 4. $V_{CC} = 3.3 \text{ V} \pm 0.3 \text{ V}$; $T_{J} = -40 ^{\circ}\text{C}$ to $+100 ^{\circ}\text{C}$, $C_{L} = 50 \text{ pF}$
 - 5. TXC (SCK Pin) = Transmit Clock
 - RXC (SC0 or SCK Pin) = Receive Clock
 - FST (SC2 Pin) = Transmit Frame Sync
 - FSR (SC1 or SC2 Pin) Receive Frame Sync
 - 6. i ck = Internal Clock
 - x ck = External Clock
 - i ck a = Internal Clock, Asynchronous Mode
 - (Asynchronous implies that TXC and RXC are two different clocks)
 - i ck s = Internal Clock, Synchronous Mode
 - (Synchronous implies that TXC and RXC are the same clock)
 - 7. bl = bit length
 - wl = word length
 - wr = word length relative

Note: In Network mode, output flag transitions can occur at the start of each time slot within the frame. In Normal mode, the output flag state is asserted for the entire frame period.

SECTION 3 PACKAGING

PIN-OUT AND PACKAGE INFORMATION

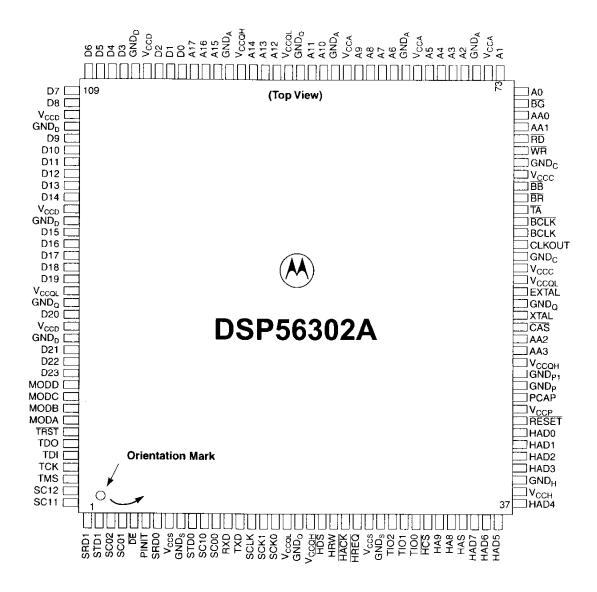

This sections provides information about the available packages for this product, including diagrams of the package pinouts and tables describing how the signals described in **Section 1** are allocated for each package.

The DSP56302A is available in two package types:

- 144-pin Thin Quad Flat Pack (TQFP)
- 196-pin Plastic Ball Grid Array (PBGA)

TQFP Package Description

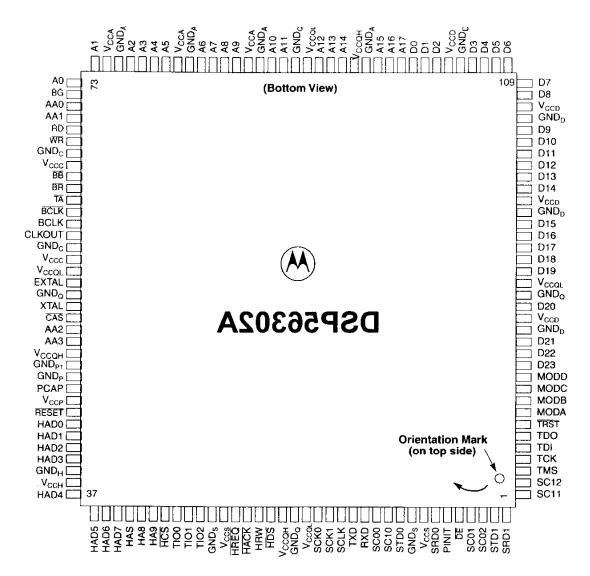

Top and bottom views of the TQFP package are shown in **Figure 3-1** and **Figure 3-2** with their pin-outs.

Note: Because of size constraints in this figure, only one name is shown for multiplexed pins. Refer to **Table 3-1** and **Table 3-2** for detailed information about pin functions and signal names.

AA0301

Figure 3-1 DSP56302A Thin Quad Flat Pack (TQFP), Top View

Note: Because of size constraints in this figure, only one name is shown for multiplexed pins. Refer to **Table 3-1** and **Table 3-2** for detailed information about pin functions and signal names.

93	A13	116	D12	139	TDO
94	A14	117	D13	140	TDI
95	V _{CCQH}	118	D14	141	TCK
96	GND _A	119	V _{CCD}	142	TMS
97	A15	120	GND_D	143	SC12 or PD2
98	A16	121	D15	144	SC11 or PD1

Note: Signal names are based on configured functionality. Most pins supply a single signal. Some pins provide a signal with dual functionality, such as the MODx/IRQx pins that select an operating mode after RESET is deasserted, but act as interrupt lines during operation. Some signals have configurable polarity; these names are shown with and without overbars, such as HAS/HAS. Some pins have two or more configurable functions; names assigned to these pins indicate the function for a specific configuration. For example, Pin 34 is data line H7 in Non-multiplexed Bus mode, data/address line HAD7 in Multiplexed Bus mode, or GPIO line PB7 when the GPIO function is enabled for this pin.

Signal names are based on configured functionality. Most connections supply a single signal. Some connections provide a signal with dual functionality, such as the MODx/IRQx pins that select an operating mode after RESET is deasserted, but act as interrupt lines during operation. Some signals have configurable polarity; these names are shown with and without overbars, such as HAS/HAS. Some connections have two or more configurable functions; names assigned to these connections indicate the function for a specific configuration. For example, connection N2 is data line H7 in Non-multiplexed Bus mode, data/address line HAD7 in Multiplexed Bus mode, or GPIO line PB7 when the GPIO function is enabled for this pin. Unlike the TQFP package, most of the GND pins are connected internally in the center of the connection array and act as heat sink for the chip. Therefore, except for GND_P and GND_{P1} that support the PLL, other

GND signals do not support individual subsystems in the chip.

PBGA Package Mechanical Drawing

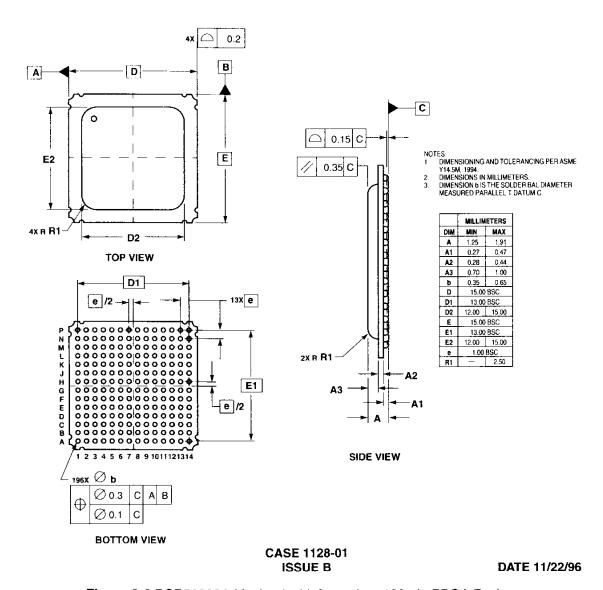

Figure 3-6 DSP56302A Mechanical Information, 196-pin PBGA Package

ORDERING DRAWINGS

Complete mechanical information regarding DSP56302A packaging is available by facsimile through Motorola's Mfax system. Call the following number to obtain information by facsimile:

(602) 244-6609

The Mfax automated system requests the following information:

- The receiving facsimile telephone number including area code or country code
- The caller's Personal Identification Number (PIN)

Note: For first time callers, the system provides instructions for setting up a PIN, which requires entry of a name and telephone number.

- The type of information requested:
 - Instructions for using the system
 - A literature order form
 - Specific part technical information or data sheets
 - Other information described by the system messages

A total of three documents may be ordered per call.

The DSP56302A 144-pin TQFP package mechanical drawing is referenced as 918-03. The reference number for the 196-pin PBGA package is 1128-01.

SECTION 4 DESIGN CONSIDERATIONS

THERMAL DESIGN CONSIDERATIONS

An estimation of the chip junction temperature, T_J, in °C can be obtained from the equation:

Equation 1: $T_J = T_A + (P_D \times R_{\theta JA})$

Where:

 T_A = ambient temperature °C

 $R_{\theta IA}$ = package junction-to-ambient thermal resistance °C/W

P_D = power dissipation in package

Historically, thermal resistance has been expressed as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

Equation 2: $R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$

Where:

 $R_{\theta JA}$ = package junction-to-ambient thermal resistance °C/W $R_{\theta JC}$ = package junction-to-case thermal resistance °C/W package case-to-ambient thermal resistance °C/W

 $R_{\theta JC}$ is device-related and cannot be influenced by the user. The user controls the thermal environment to change the case-to-ambient thermal resistance, $R_{\theta CA}$. For example, the user can change the air flow around the device, add a heat sink, change the mounting arrangement on the Printed Circuit Board (PCB), or otherwise change the thermal dissipation capability of the area surrounding the device on a PCB. This model is most useful for ceramic packages with heat sinks; some 90% of the heat flow is dissipated through the case to the heat sink and out to the ambient environment. For ceramic packages, in situations where the heat flow is split between a path to the case and an alternate path through the PCB, analysis of the device thermal performance may need the additional modeling capability of a system level thermal simulation tool.

Thermal Design Considerations

The thermal performance of plastic packages is more dependent on the temperature of the PCB to which the package is mounted. Again, if the estimations obtained from $R_{\theta JA}$ do not satisfactorily answer whether the thermal performance is adequate, a system level model may be appropriate.

A complicating factor is the existence of three common ways for determining the junction-to-case thermal resistance in plastic packages:

- To minimize temperature variation across the surface, the thermal resistance
 is measured from the junction to the outside surface of the package (case)
 closest to the chip mounting area when that surface has a proper heat sink.
- To define a value approximately equal to a junction-to-board thermal resistance, the thermal resistance is measured from the junction to where the leads are attached to the case.
- If the temperature of the package case (T_T) is determined by a thermocouple, the thermal resistance is computed using the value obtained by the equation (T_I - T_T)/P_D.

As noted above, the junction-to-case thermal resistances quoted in this data sheet are determined using the first definition. From a practical standpoint, that value is also suitable for determining the junction temperature from a case thermocouple reading in forced convection environments. In natural convection, using the junction-to-case thermal resistance to estimate junction temperature from a thermocouple reading on the case of the package will estimate a junction temperature slightly hotter than actual temperature. Hence, the new thermal metric, Thermal Characterization Parameter or Ψ_{JT} , has been defined to be $(T_J-T_T)/P_D$. This value gives a better estimate of the junction temperature in natural convection when using the surface temperature of the package. Remember that surface temperature readings of packages are subject to significant errors caused by inadequate attachment of the sensor to the surface and to errors caused by heat loss to the sensor. The recommended technique is to attach a 40-gauge thermocouple wire and bead to the top center of the package with thermally conductive epoxy.

ELECTRICAL DESIGN CONSIDERATIONS

CAUTION

This device contains protective circuitry to guard against damage due to high static voltage or electrical fields. However, normal precautions are advised to avoid application of any voltages higher than maximum rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (e.g., either GND or V_{CC}).

Use the following list of recommendations to assure correct DSP operation:

- Provide a low-impedance path from the board power supply to each V_{CC} pin on the DSP, and from the board ground to each GND pin.
- Use at least six 0.01–0.1 μ F bypass capacitors positioned as close as possible to the four sides of the package to connect the V_{CC} power source to GND.
- Ensure that capacitor leads and associated printed circuit traces that connect to the chip V_{CC} and GND pins are less than 0.5 in per capacitor lead.
- Use at least a four-layer PCB with two inner layers for V_{CC} and GND.
- Because the DSP output signals have fast rise and fall times, PCB trace lengths should be minimal. This recommendation particularly applies to the address and data buses as well as the IRQA, IRQB, IRQC, IRQD, TA, and BG pins. Maximum PCB trace lengths on the order of 6 inches are recommended.
- Consider all device loads and parasitic capacitance due to PCB traces when
 calculating capacitance. This is especially critical in systems with higher
 capacitive loads that could create higher transient currents in the V_{CC} and
 GND circuits.
- All inputs must be terminated (i.e., not allowed to float) using CMOS levels, except for the three pins with internal pull-up resistors (TRST, TMS, DE).
- Take special care to minimize noise levels on V_{CCP}, GND_P, and GND_{P1} pins.
- The following pins must be asserted after power-up: RESET and TRST.
- If multiple DSP56302A devices are on the same board, check for cross-talk or excessive spikes on the supplies due to synchronous operation of the devices.

Power Consumption Considerations

 RESET must be asserted when the chip is powered up. A stable EXTAL signal should be supplied before deassertion of RESET.

POWER CONSUMPTION CONSIDERATIONS

Power dissipation is a key issue in portable DSP applications. Some of the factors which affect current consumption are described in this section. Most of the current consumed by CMOS devices is alternating current (ac), which is charging and discharging the capacitances of the pins and internal nodes.

Current consumption is described by the formula:

Equation 3: $I = C \times V \times f$

where: C = node/pin capacitance

V = voltage swing

f = frequency of node/pin toggle

Example 4-1 Current Consumption

For a Port A address pin loaded with 50 pF capacitance, operating at 3.3 V, and with a 66 MHz clock, toggling at its maximum possible rate (33 MHz), the current consumption is:

Equation 4:
$$I = 50 \times 10^{-12} \times 3.3 \times 33 \times 10^6 = 5.48 \text{ mA}$$

The Maximum Internal Current (I_{CCI} max) value reflects the typical possible switching of the internal buses on best-case operation conditions, which is not necessarily a real application case. The Typical Internal Current (I_{CCI} typ) value reflects the average switching of the internal buses on typical operating conditions.

For applications that require very low current consumption:

- Set the EBD bit when not accessing external memory.
- Minimize external memory accesses, and use internal memory accesses.
- Minimize the number of pins that are switching.
- Minimize the capacitive load on the pins.
- Connect the unused inputs to pull-up or pull-down resistors.
- Disable unused peripherals.
- Disable unused pin activity (e.g., CLKOUT, XTAL).

One way to evaluate power consumption is to use a current per MIPS measurement methodology to minimize specific board effects (i.e., to compensate for measured board current not caused by the DSP). A benchmark power consumption test algorithm is listed in **Appendix A**. Use the test algorithm, specific test current measurements, and the following equation to derive the current per MIPS value:

Equation 5: $1/MIPS = I/MHz = (1_{typF2} - I_{typF1})/(F2 - F1)$

where:

 I_{typF2} = current at F2 I_{typF1} = current at F1

F2 = high frequency (any specified operating frequency)

F1 = low frequency (any specified operating frequency less than F2)

Note: F1 should be significantly less than F2. For example, F2 could be 66 MHz and F1 could be 33 MHz. The degree of difference between F1 and F2 determines the amount of precision with which the current rating can be determined for an application.

PLL PERFORMANCE ISSUES

The following explanations should be considered as general observations on expected PLL behavior. There is no testing that verifies these exact numbers. These observations were measured on a limited number of parts and were not verified over the entire temperature and voltage ranges.

Phase Skew Performance

The phase skew of the PLL is defined as the time difference between the falling edges of EXTAL and CLKOUT for a given capacitive load on CLKOUT, over the entire process, temperature and voltage ranges. As defined in **Figure 2-2** on page 2-7, for input frequencies greater than 15 MHz and the MF \leq 4, this skew is greater than or equal to 0.0 ns and less than 1.8 ns; otherwise, this skew is not guaranteed. However, for MF < 10 and input frequencies greater than 10 MHz, this skew is between -1.4 ns and +3.2 ns.

Phase Jitter Performance

The phase jitter of the PLL is defined as the variations in the skew between the falling edges of EXTAL and CLKOUT for a given device in specific temperature, voltage, input frequency, MF, and capacitive load on CLKOUT. These variations are a result of the PLL locking mechanism. For input frequencies greater than 15 MHz and MF \leq 4, this jitter is less than ± 0.6 ns; otherwise, this jitter is not guaranteed. However, for MF < 10 and input frequencies greater than 10 MHz, this jitter is less than ± 2 ns.

Frequency Jitter Performance

The frequency jitter of the PLL is defined as the variation of the frequency of CLKOUT. For small MF (MF < 10) this jitter is smaller than 0.5%. For mid-range MF (10 < MF < 500) this jitter is between 0.5% and approximately 2%. For large MF (MF > 500), the frequency jitter is 2–3%.

Input (EXTAL) Jitter Requirements

The allowed jitter on the frequency of EXTAL is 0.5%. If the rate of change of the frequency of EXTAL is slow (i.e., it does not jump between the minimum and maximum values in one cycle) or the frequency of the jitter is fast (i.e., it does not stay at an extreme value for a long time), then the allowed jitter can be 2%. The phase and frequency jitter performance results are only valid if the input jitter is less than the prescribed values.

SECTION 5 ORDERING INFORMATION

Consult a Motorola Semiconductor sales office or authorized distributor to determine product availability and to place an order.

APPENDIX A

POWER CONSUMPTION BENCHMARK

The following benchmark program permits evaluation of DSP power usage in a test situation. It enables the PLL, disables the external clock, and uses repeated Multiply-Accumulate (MAC) instructions with a set of synthetic DSP application data to emulate intensive sustained DSP operation.

APPENDIX B BOOTSTRAP PROGRAMS

```
; BOOTSTRAP CODE FOR DSP56302 - (C) Copyright 1995 Motorola Inc.
 Revised June, 29 1995.
; Bootstrap through the Host Interface, External EPROM or SCI.
; This is the Bootstrap program contained in the DSP56302 192-word Boot
; ROM. This program can load any program RAM segment from an external
; EPROM, from the Host Interface or from the SCI serial interface.
; If MD:MC:MB:MA=1000, then the Boot ROM is bypassed and the DSP56302 will
; start fetching instructions beginning with the address $8000 assuming that
; an external memory of SRAM type is used. The accesses will be performed
; using 31 wait states with no address attributes selected (default area).
; If MC:MB:MA=001, then it loads a program RAM segment from consecutive
; byte-wide P memory locations, starting at P:$D00000 (bits 7-0).
; The memory is selected by the Address Attribute AA1 and is accessed with
; 31 wait states.
; The EPROM bootstrap code expects to read 3 bytes
; specifying the number of program words, 3 bytes specifying the address
; to start loading the program words and then 3 bytes for each program
; word to be loaded. The number of words, the starting address and the
; program words are read least significant byte first followed by the
; mid and then by the most significant byte.
; The program words will be condensed into 24-bit words and stored in
; contiguous PRAM memory locations starting at the specified starting
: address.
; After reading the program words, program execution starts from the same
; address where loading started.
; If MC:MB:MA=010, then it loads the program RAM from the SCI interface.
; The number of program words to be loaded and the starting address must
; be specified. The SCI bootstrap code expects to receive 3 bytes
```

```
; specifying the number of program words, 3 bytes specifying the address
; to start loading the program words and then 3 bytes for each program
; word to be loaded. The number of words, the starting address and the
; program words are received least significant byte first followed by the
; mid and then by the most significant byte. After receiving the
; program words, program execution starts in the same address where
; loading started. The SCI is programmed to work in asynchronous mode
; with 8 data bits, 1 stop bit and no parity. The clock source is
; external and the clock frequency must be 16x the baud rate.
; After each byte is received, it is echoed back through the SCI
; transmitter.
; If MC:MB:MA=100, then it loads the program RAM from the Host
; Interface programmed to operate in the ISA mode.
; The HOST ISA bootstrap code expects to read a 24-bit word
; specifying the number of program words, a 24-bit word specifying the address
; to start loading the program words and then a 24\text{-bit} word for each program
; word to be loaded. The program words will be stored in
; contiguous PRAM memory locations starting at the specified starting address.
; After reading the program words, program execution starts from the same
; address where loading started.
; The Host Interface bootstrap load program may be stopped by
; setting the Host Flag 0 (HF0). This will start execution of the loaded
; program from the specified starting address.
; If MC:MB:MA=101, then it loads the program RAM from the Host
; Interface programmed to operate in the HC11 non multiplexed mode.
; The HOST HC11 bootstrap code expects to read a 24-bit word
; specifying the number of program words, a 24-bit word specifying the address
; to start loading the program words and then a 24-bit word for each program
; word to be loaded. The program words will be stored in
; contiguous PRAM memory locations starting at the specified starting address.
; After reading the program words, program execution starts from the same
; address where loading started.
; The Host Interface bootstrap load program may be stopped by
; setting the Host Flag 0 (HF0). This will start execution of the loaded
; program from the specified starting address.
; If MC:MB:MA=110, then it loads the program RAM from the Host
: Interface programmed to operate in the 8051 multiplexed bus mode,
```

```
; in double-strobe pin configuration.
; The HOST 8051 bootstrap code expects accesses that are byte wide.
; The HOST 8051 bootstrap code expects to read 3 bytes forming a 24\text{-bit} word
; specifying the number of program words, 3 bytes forming a 24-bit word
; specifying the address to start loading the program words and then 3\ \mathrm{bytes}
; forming 24-bit words for each program word to be loaded.
; The program words will be stored in contiguous PRAM memory locations
; starting at the specified starting address.
; After reading the program words, program execution starts from the same
; address where loading started.
; The Host Interface bootstrap load program may be stopped by setting the
; Host Flag 0 (HF0). This will start execution of the loaded program from
; the specified starting address.
; The base address of the {\tt HI08} in multiplexed mode is {\tt 0x80} and is not modified
; by the bootstrap code. All the address lines are enabled and should be
; connected accordingly.
; If \mbox{MC:MB:MA=111}, then it loads the program RAM from the Host
; Interface programmed to operate in the MC68302 bus mode,
; in single-strobe pin configuration.
; The HOST MC68302 bootstrap code expects accesses that are byte wide.
; The HOST MC68302 bootstrap code expects to read 3 bytes forming a 24-bit word
; specifying the number of program words, 3 bytes forming a 24-bit word
; specifying the address to start loading the program words and then 3 bytes
; forming 24-bit words for each program word to be loaded.
; The program words will be stored in contiguous PRAM memory locations
; starting at the specified starting address.
; After reading the program words, program execution starts from the same
; address where loading started.
; The Host Interface bootstrap load program may be stopped by setting the
; Host Flag 0 (HF0). This will start execution of the loaded program from
; the specified starting address.
