

MX66V2000

Low Power/Voltage 512k x 8 CMOS SRAM

FEATURES

- ☑ Wide operation voltage
2.4V ~ 5.5V
- ☑ Low power consumption

V _{cc} =3.0V	20mA (Max.) write current
	2mA (Max.) read current
	1uA (Typ.) CMOS standby current
V _{cc} =5.0V	30mA (Max.) write current
	5mA (Max.) read current
	1uA (Typ.) CMOS standby current
- ☑ High speed access time
70ns (Max.)
- ☑ Input levels are CMOS-compatible
- ☑ Automatic power down when chip is deselected
- ☑ Three state outputs
- ☑ Fully static operation
- ☑ Data retention supply voltage as low as 1.5V
- ☑ Easy expansion with $\overline{CE1}$, CE2, and \overline{OE} options
- ☑ All I/O pins are 3V tolerant

DESCRIPTION

The MX66V2000 is a high performance, low power CMOS Static Random Access Memory organized as 262,144 words by 8 bits and operates from a wide range of 5.0Volts to 3.0Volts supply voltage. Advanced CMOS technology and circuit techniques provide both high speed and low power features with a typical CMOS standby current of 0.1uA and maximum access time of 70ns in 3.3V operation. Easy memory expansion is provided by an active LOW chip enable($\overline{CE1}$), an active HIGH chip enable (CE2), and active LOW output enable (\overline{OE}) and three-state output drivers. The MX66V2000 has an automatic power down feature, reducing the power consumption significantly when chip is deselected. The MX66V2000 is available in the JEDEC standard 32 pin 600mil Plastic DIP, 525mil Plastic SOP, and 8mmx13.4mm STSOP, and 8mmx20mm TSOP.

PIN DESCRIPTIONS

A₀-A₁₇ Address Input

These 18 address input select one of the 262,144 x 8-bit words in the RAM.

\overline{CE}_1 Chip Enable 1 Input

CE₂ Chip Enable 2 Input

\overline{CE}_1 is active LOW and CE2 is active HIGH. Both chip enables must be active to read from or write to the device. If either chip enable is not active, the device is deselected and is in a standby power mode. The DQ pins will be in the high-impedance state when the device is deselected.

\overline{WE} Write Enable Input

The write enable input is active LOW and controls read and write operations. With the chip selected, when \overline{WE} is HIGH and \overline{OE} is LOW, output data will be present on the DQ pins; when \overline{WE} is LOW, the data present on the DQ pins will be written into the selected memory location.

\overline{OE} Output Enable Input

The output enable input is active LOW. If the output enable is active while the chip is selected and the write enable is inactive, data will be present on the DQ pins and they will be enabled. The DQ pins will be in the high impedance state when \overline{OE} is inactive.

DQ₀ - DQ₇ Data Input/Output Ports

These 8 bi-directional ports are used to read data from or write data into the RAM.

READ CYCLE1 (1,2,4)

READ CYCLE2 (1,3,4)

READ CYCLE3 (1,4)

NOTES:

1. \overline{WE} is high for read Cycle.
2. Device is continuously selected when $\overline{CE1} = V_{IL}$ and $CE2 = V_{IH}$.
3. Address valid prior to or coincident with $\overline{CE1}$ transition low and/or CE2 transition high.
4. $\overline{OE} = V_{IL}$.
5. Transition is measured $\pm 500mV$ from steady state with $C_L = 5pF$ as shown in Figure 1B. The parameter is guaranteed but not 100% tested.

SWITCHING WAVEFORMS (WRITE CYCLE)

WRITE CYCLE1 (1)

WRITE CYCLE2^(1,6)

NOTES:

- \overline{WE} must be high during address transitions.
- The internal write time of the memory is defined by the overlap of $\overline{CE1}$ and $CE2$ active and \overline{WE} low. All signals must be active to initiate a write and any one signal can terminate a write by going inactive. The data input setup and hold timing should be referenced to the second transition edge of the signal that terminates the write.
- T_{WR} is measured from the earlier of $\overline{CE1}$ or \overline{WE} going high or $CE2$ going low at the end of write cycle.
- During this period, DQ pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
- If the $\overline{CE1}$ low transition or the $CE2$ high transition occurs simultaneously with the \overline{WE} low transitions or after the \overline{WE} transition, output remain in a high impedance state.
- \overline{OE} is continuously low ($OE = V_{IL}$).
- D_{OUT} is the same phase of write data of this write cycle.
- D_{OUT} is the read data of next address.
- If $\overline{CE1}$ is low and $CE2$ is high during this period, DQ pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
- Transition is measured $\pm 500mV$ from steady state with $C_L = 5pF$ as shown in Figure 1b. The parameter is guaranteed but not 100% tested.
- T_{CW} is measured from the later of $\overline{CE1}$ going low or $CE2$ going high to the end of write.
