> M29W641DU

## 64 Mbit (4Mb x16, Uniform Block) 3V Supply Flash Memory <br> OBSOLETE PRODUCT

## FEATURES SUMMARY

■ SUPPLY VOLTAGE

- $\mathrm{V}_{\mathrm{CC}}=2.7 \mathrm{~V}$ to 3.6V Core Power Supply
$-\mathrm{V}_{\mathrm{CCQ}}=1.8 \mathrm{~V}$ to 3.6 V for Input/Output
- VPP=12 V for Fast Program (optional)

■ ACCESS TIME: 90, 100 and 120ns

- PROGRAMMING TIME
- $10 \mu$ stypical
- Double Word Program option

■ 128 UNIFORM, 32-KWord MEMORY BLOCKS

- PROGRAM/ERASE CONTROLLER
- Embedded Program and Erase algorithms
- ERASE SUSPEND and RESUME MODES
- Read and Program another Block during Erase Suspend
■ UNLOCK BYPASS PROGRAM COMMAND
- Faster Production/Batch Programming

■ WRITE PROTECT OPTIONS

- M29W641DH: WP Pin for Write Protection of Highest Address Block
- M29W641DL: $\overline{W P}$ Pin for Write Protection of Lowest Address Block
- M29W641DU: No Write Protection

■ TEMPORARY BLOCK UNPROTECTION MODE

- COMMON FLASH INTERFACE
- EXTENDED MEMORY BLOCK
- Extra block used as security block or to store additional information
■ LOW POWER CONSUMPTION
- Standby and Automatic Standby
- ELECTRONIC SIGNATURE
- Manufacturer Code: 0020h
- Device Code M29W641D: 22C7h

## SUMMARY DESCRIPTION

The M29W641D is a $64 \mathrm{Mbit}(4 \mathrm{Mb} \times 16)$ non-volatile memory that can be read, erased and reprogrammed. These operations can be performed using a single, low voltage, 2.7 V to $3.6 \mathrm{~V} \mathrm{~V}_{\mathrm{Cc}}$ supply for the circuitry and a 1.8 V to $3.6 \mathrm{~V} \mathrm{~V}_{\mathrm{CCQ}}$ supply for the Input/Output pins. An optional 12 V VPP power supply is provided to speed up customer programming.
On power-up the memory defaults to its Read mode where it can be read in the same way as a ROM or EPROM.
The highest address block of the M29W641DH or the lowest address block of the M29W641DL can be protected from accidental programming or erasure using the $\overline{W P}$ pin (if $\overline{W P}=V_{I L}$ ). The M29W641DU does not feature the $\overline{\mathrm{WP}}$ pin.
Each block can be erased independently so it is possible to preserve valid data while old data is erased. The blocks can be protected to prevent accidental Program or Erase commands from modifying the memory. Program and Erase commands are written to the Command Interface of the memory. An on-chip Program/Erase Controller simplifies the process of programming or erasing the memory by taking care of all of the special operations that are required to update the memory contents. The end of a program or erase operation can be detected and any error conditions identified. The command set required to control the memory is consistent with JEDEC standards.
The M29W641D has an extra block, the Extended Block, (of 32 KWords) that can be accessed using a dedicated command. The Extended Block can be protected and so is useful for storing security information. However the protection is not reversible, once protected the protection cannot be undone.
Chip Enable, Output Enable and Write Enable signals control the bus operation of the memory. They allow simple connection to most microprocessors, often without additional logic.
The memory is offered in a 48-pin TSOP package (M29W641DL and M29W641DH) or in a 63-ball TFBGA package (M29W641DU). All devices are delivered with all the bits erased (set to 1).

Note: 1. Balls are shorted together via the substrate but not connected to the die.

## SIGNAL DESCRIPTIONS

See Figure 2, Logic Diagram, and Table 1, Signal Names, for a brief overview of the signals connected to this device.
Address Inputs (A0-A21). The Address Inputs select the cells in the memory array to access during Bus Read operations. During Bus Write operations they control the commands sent to the Command Interface of the Program/Erase Controller.
Data Inputs/Outputs (DQ0-DQ7). The Data I/O outputs the data stored at the selected address during a Bus Read operation. During Bus Write operations they represent the commands sent to the Command Interface of the Program/Erase Controller.
Data Inputs/Outputs (DQ8-DQ15). The Data I/O outputs the data stored at the selected address during a Bus Read operation. During Bus Write operations the Command Register does not use these bits. When reading the Status Register these bits should be ignored.
Chip Enable ( $\overline{\mathrm{E}}$ ). The Chip Enable, $\overline{\mathrm{E}}$, activates the memory, allowing Bus Read and Bus Write operations to be performed. When Chip Enable is High, $\mathrm{V}_{\mathrm{IH}}$, all other pins are ignored.
Output Enable ( $\overline{\mathrm{G}})$. The Output Enable, $\overline{\mathrm{G}}$, controls the Bus Read operation of the memory.
Write Enable ( $\overline{\mathrm{W}}$ ). The Write Enable, $\overline{\mathrm{W}}$, controls the Bus Write operation of the memory's Command Interface.
Write Protect ( $\overline{\mathrm{WP}}$ ). The Write Protect pin is available in the M29W641DH and M29W641DL only. It provides a hardware method of protecting the highest address block for the M29W641DH and the lowest address block for the M29W641DL. The Write Protect pin must not be left floating or unconnected.
When Write Protect is Low, $\mathrm{V}_{\mathrm{IL}}$, the memory protects either the highest or lowest address block; Program and Erase operations in this block are ignored while Write Protect is Low.
When Write Protect is High, $\mathrm{V}_{\mathrm{IH}}$, the memory reverts to the previous protection status for this block. Program and Erase operations can now modify the data in this block unless the block is protected using Block Protection.
Ready/Busy Output (R $\bar{B}$ ). The Ready/Busy pin is an open-drain output that can be used to identify when the device is performing a Program or Erase operation. During Program or Erase operations Ready/Busy is Low, Vol. Ready/Busy is high-impedance during Read mode, Auto Select mode and Erase Suspend mode.
After a Hardware Reset, Bus Read and Bus Write operations cannot begin until Ready/Busy be-
comes high-impedance. See Table 13 and Figure 12, Reset/Block Temporary Unprotect AC Characteristics.
The use of an open-drain output allows the Ready/ Busy pins from several memories to be connected to a single pull-up resistor. A Low will then indicate that one, or more, of the memories is busy.
Reset/Block Temporary Unprotect ( $\overline{\mathrm{RP}}$ ). The
Reset/Block Temporary Unprotect pin can be used to apply a Hardware Reset to the memory or to temporarily unprotect all Blocks that have been protected.
Note that if Write Protect $(\overline{\mathrm{WP}})$ is at $\mathrm{V}_{\mathrm{IL}}$, then one of the two outermost blocks will remain protected even if $R P$ is at $V_{\text {ID }}$.
A Hardware Reset is achieved by holding Reset/ Block Temporary Unprotect Low, $\mathrm{V}_{\mathrm{IL}}$, for at least tplpx. After Reset/Block Temporary Unprotect goes High, $\mathrm{V}_{\mathrm{IH}}$, the memory will be ready for Bus Read and Bus Write operations after tphel or $t_{\text {RHEL }}$, whichever occurs last. See Table 13 and Figure 12, Reset/Block Temporary Unprotect AC Characteristics, for more details.
Holding $\overline{R P}$ at $V_{\text {ID }}$ will temporarily unprotect the protected Blocks in the memory. Program and Erase operations on all blocks will be possible. The transition from $\mathrm{V}_{\mathrm{IH}}$ to $\mathrm{V}_{\mathrm{ID}}$ must be slower than tphehr.
$\mathbf{V}_{\mathbf{P P}}\left(\mathrm{V}_{\mathrm{PP}}\right)$. When the $\mathrm{V}_{\mathrm{PP}}$ pin is raised to $\mathrm{V}_{\mathrm{PPH}}$ the memory automatically enters the Unlock Bypass mode. When the pin is returned to $\mathrm{V}_{\text {IH }}$ or $\mathrm{V}_{\text {IL }}$ normal operation resumes. During Unlock Bypass Program operations the memory draws Ipp from the pin to supply the programming circuits. See the description of the Unlock Bypass command in the Command Interface section. The transitions from $\mathrm{V}_{I H}$ to $\mathrm{V}_{\mathrm{PP}}$ and from $\mathrm{V}_{\mathrm{PP}}$ to $\mathrm{V}_{I H}$ must be slower than tvhvpp, see Figure 13.
Never raise the pin to VPP from any mode except Read mode, otherwise the memory may be left in an indeterminate state.
 vides the power supply for all operations (Read, Program and Erase).
The Command Interface is disabled when the $\mathrm{V}_{\mathrm{CC}}$ Supply Voltage is less than the Lockout Voltage, VLKO. This prevents Bus Write operations from accidentally damaging the data during power up, power down and power surges. If the Program/ Erase Controller is programming or erasing during this time then the operation aborts and the memory contents being altered will be invalid.
$V_{C C Q}$ Supply Voltage (1.8V to 3.6V). VCCQ provides the power supply to the I/O pins and enables all Outputs to be powered independently of $\mathrm{V}_{\mathrm{CC}}$.
$\mathrm{V}_{C C Q}$ can be tied to $\mathrm{V}_{\mathrm{CC}}$ or can use a separate supply.
$\mathrm{V}_{\text {SS }}$ Ground. $\mathrm{V}_{\text {SS }}$ is the reference for all voltage measurements. The device features two $\mathrm{V}_{\mathrm{ss}}$ pins which must be both connected to the system ground.
Note: Each device in a system should have $\mathrm{V}_{\mathrm{CC}}, \mathrm{V}_{\mathrm{CCQ}}$ and $\mathrm{V}_{\mathrm{PP}}$ decoupled from $\mathrm{V}_{\mathrm{SS}}$ with a
$0.1 \mu \mathrm{~F}$ ceramic capacitor close to the pin for current surge protection (high frequency, inherently low inductance capacitors should be as close as possible to the device). See Figure 8, AC Measurement Load Circuit. The PCB trace widths should be sufficient to carry the required VPP program and erase currents. See Table 9, DC Characteristics.

Table 2. Bus Operations

| Operation | $\overline{\mathrm{E}}$ | $\overline{\mathbf{G}}$ | W | Address Inputs A0-A21 | Data Inputs/Outputs DQ15-DQ0 |

[^0]
## M29W641DH, M9W641DL, M29W641DU

## BUS OPERATIONS

There are five standard bus operations that control the device. These are Bus Read, Bus Write, Output Disable, Standby and Automatic Standby. See Table 2, Bus Operations, for a summary. Typically glitches of less than 5ns on Chip Enable or Write Enable are ignored by the memory and do not affect bus operations.
Bus Read. Bus Read operations read from the memory cells, or specific registers in the Command Interface. A valid Bus Read operation involves setting the desired address on the Address Inputs, applying a Low signal, $\mathrm{V}_{\text {IL }}$, to Chip Enable and Output Enable and keeping Write Enable High, $\mathrm{V}_{\mathrm{IH}}$. The Data Inputs/Outputs will output the value, see Figure 9, Read Mode AC Waveforms, and Table 10, Read AC Characteristics, for details of when the output becomes valid.
Bus Write. Bus Write operations write to the Command Interface. A valid Bus Write operation begins by setting the desired address on the Address Inputs. The Address Inputs are latched by the Command Interface on the falling edge of Chip Enable or Write Enable, whichever occurs last. The Data Inputs/Outputs are latched by the Command Interface on the rising edge of Chip Enable or Write Enable, whichever occurs first. Output Enable must remain High, $\mathrm{V}_{\mathrm{IH}}$, during the whole Bus Write operation. See Figure 10 and Figure 11, Write AC Waveforms, and Table 11 and Table 12, Write AC Characteristics, for details of the timing requirements.
Output Disable. The Data Inputs/Outputs are in the high impedance state when Output Enable is High, $\mathrm{V}_{\mathrm{IH}}$.
Standby. When Chip Enable is High, $\mathrm{V}_{\mathrm{IH}}$, the memory enters Standby mode and the Data Inputs/Outputs pins are placed in the high-impedance state. To reduce the Supply Current to the Standby Supply Current, ICC2, Chip Enable should
be held within $\mathrm{V}_{\mathrm{CC}} \pm 0.2 \mathrm{~V}$. For the Standby current level see Table 9, DC Characteristics.
During program or erase operations the memory will continue to use the Program/Erase Supply Current, ICC3, for Program or Erase operations until the operation completes.
Automatic Standby. If CMOS levels ( $\mathrm{V}_{\mathrm{CC}} \pm 0.2 \mathrm{~V}$ ) are used to drive the bus and the bus is inactive for 300 ns or more the memory enters Automatic Standby where the internal Supply Current is reduced to the Standby Supply Current, Icc2. The Data Inputs/Outputs will still output data if a Bus Read operation is in progress.

## Special Bus Operations

Additional bus operations can be performed to read the Electronic Signature and also to apply and remove Block Protection. These bus operations are intended for use by programming equipment and are not usually used in applications. They require $\mathrm{V}_{\text {ID }}$ to be applied to some pins.
Electronic Signature. The memory has two codes, the manufacturer code and the device code, that can be read to identify the memory. These codes can be read by applying the signals listed in Table 2, Bus Operations.
Block Protect and Chip Unprotect. Groups of blocks can be protected against accidental Program or Erase. The whole chip can be unprotected to allow the data inside the blocks to be changed.
Write Protect ( $\overline{W P}$ ) can be used to protect one of the outermost blocks. When Write Protect ( $\overline{\mathrm{WP}}$ ) is at $\mathrm{V}_{\text {IL }}$ one of the two outermost blocks is protected and remains protected regardless of the Block Protection Status or the Reset/Block Temporary Unprotect pin status. For the M29W641DH, it is the highest addressed block that can be protected. For the M29W641DL, it is the lowest.
Block Protect and Chip Unprotect operations are described in Appendix D.

## COMMAND INTERFACE

All Bus Write operations to the memory are interpreted by the Command Interface. Commands consist of one or more sequential Bus Write operations. Failure to observe a valid sequence of Bus Write operations will result in the memory returning to Read mode. The long command sequences are imposed to maximize data security.
See Table 3 for a summary of the commands.

## Read/Reset Command

The Read/Reset command returns the memory to its Read mode where it behaves like a ROM or EPROM. It also resets the errors in the Status Register. Either one or three Bus Write operations can be used to issue the Read/Reset command.
The Read/Reset command can be issued, between Bus Write cycles before the start of a program or erase operation, to return the device to read mode. If the Read/Reset command is issued during the timeout of a Block erase operation then the memory will take up to $10 \mu$ s to abort. During the abort period no valid data can be read from the memory. The Read/Reset command will not abort an Erase operation when issued while in Erase Suspend.

## Auto Select Command

The Auto Select command is used to read the Manufacturer Code, the Device Code, the Block Protection Status and the Extended Memory Block Verify Code. Three consecutive Bus Write operations are required to issue the Auto Select command. Once the Auto Select command is issued the memory remains in Auto Select mode until a Read/Reset command is issued. Read CFI Query and Read/Reset commands are accepted in Auto Select mode, all other commands are ignored.
In Auto Select mode the Manufacturer Code can be read using a Bus Read operation with $\mathrm{A} 0=\mathrm{V}_{\text {IL }}$ and $\mathrm{A} 1=\mathrm{V}_{I L}$. The other address bits may be set to either $\mathrm{V}_{\mathrm{IL}}$ or $\mathrm{V}_{\mathrm{IH}}$. The Manufacturer Code for STMicroelectronics is 0020h.
The Device Code can be read using a Bus Read operation with $A 0=V_{I H}$ and $A 1=V_{I L}$. The other address bits may be set to either $\mathrm{V}_{\mathrm{IL}}$ or $\mathrm{V}_{\mathrm{IH}}$. The Device Code for the M29W641D is 22C7h.
The Block Protection Status of each block can be read using a Bus Read operation with $A 0=\mathrm{V}_{\mathrm{IL}}$, $\mathrm{A} 1=\mathrm{V}_{\mathrm{IH}}$, and $\mathrm{A} 12-\mathrm{A} 21$ specifying the address of the block. The other address bits may be set to either $\mathrm{V}_{\mathrm{IL}}$ or $\mathrm{V}_{\mathrm{IH}}$. If the addressed block is protected then 01h is output on Data Inputs/Outputs DQ0DQ7, otherwise 00h is output.

## Read CFI Query Command

The Read CFI Query Command is used to read data from the Common Flash Interface (CFI) Memory Area. This command is valid when the de-
vice is in the Read Array mode, or when the device is in Autoselected mode.
One Bus Write cycle is required to issue the Read CFI Query Command. Once the command is issued subsequent Bus Read operations read from the Common Flash Interface Memory Area.
The Read/Reset command must be issued to return the device to the previous mode (the Read Array mode or Autoselected mode). A second Read/ Reset command would be needed if the device is to be put in the Read Array mode from Autoselected mode.
See Appendix B, Table 18 to Table 23 for details on the information contained in the Common Flash Interface (CFI) memory area.

## Program Command

The Program command can be used to program a value to one address in the memory array at a time. The command requires four Bus Write operations, the final write operation latches the address and data, and starts the Program/Erase Controller.
If the address falls in a protected block then the Program command is ignored, the data remains unchanged. The Status Register is never read and no error condition is given.
During the program operation the memory will ignore all commands. It is not possible to issue any command to abort or pause the operation. Typical program times are given in Table 4. Bus Read operations during the program operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.
After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.
Note that the Program command cannot change a bit set at '0' back to '1'. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

## Fast Program Commands

There is a Fast Program command available to improve the programming throughput, by writing several adjacent words or bytes in parallel: the Double Word Program command.
Double Word Program Command. The Double Word Program command is used to write a page of two adjacent words in parallel. The two words must differ only for the address A0. Programming should not be attempted when $\mathrm{V}_{\mathrm{PP}}$ is not at $\mathrm{V}_{\mathrm{PPH}}$.

Three bus write cycles are necessary to issue the Double Word Program command.
■ The first bus cycle sets up the Double Word Program Command.

- The second bus cycle latches the Address and the Data of the first word to be written.
- The third bus cycle latches the Address and the Data of the second word to be written and starts the Program/Erase Controller.
After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs Bus Read operations will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.
Note that the Fast Program commands cannot change a bit set at ' 0 ' back to ' 1 '. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to ' 1 '.
Typical Program times are given in Table 4, Program, Erase Times and Program, Erase Endurance Cycles.

## Unlock Bypass Command

The Unlock Bypass command is used in conjunction with the Unlock Bypass Program command to program the memory faster than with the standard program commands. When the cycle time to the device is long (as with some EPROM programmers) considerable time saving can be made by using these commands. Three Bus Write operations are required to issue the Unlock Bypass command.
Once the Unlock Bypass command has been issued the memory enters Unlock Bypass mode. When in this mode the memory can be read as if in Read mode.
When $\mathrm{V}_{\text {PPH }}$ is applied to the VPp pin the memory automatically enters the Unlock Bypass mode and the Unlock Bypass Program command can be issued immediately.

## Unlock Bypass Program Command

The Unlock Bypass Program command can be used to program one address in the memory array at a time. The command requires two Bus Write operations, the final write operation latches the address and data, and starts the Program/Erase Controller.
A Program operation initiated by issuing the Unlock Bypass Program command is identical to a Program operation initiated by issuing the Program command. It cannot be aborted and a Bus Read operation will output the Status Register. See the Program Command paragraph for further details.

## Unlock Bypass Reset Command

The Unlock Bypass Reset command can be used to return to Read/Reset mode from Unlock Bypass Mode. Two Bus Write operations are required to issue the Unlock Bypass Reset command. Read/ Reset command does not exit from Unlock Bypass Mode.

## Chip Erase Command

The Chip Erase command can be used to erase the entire chip. Six Bus Write operations are required to issue the Chip Erase Command and start the Program/Erase Controller.
If any blocks are protected then these are ignored and all the other blocks are erased. If all of the blocks are protected the Chip Erase operation appears to start but will terminate within about $100 \mu \mathrm{~s}$, leaving the data unchanged. No error condition is given when protected blocks are ignored.
During the erase operation the memory will ignore all commands, including the Erase Suspend command. It is not possible to issue any command to abort the operation. Typical chip erase times are given in Table 4. All Bus Read operations during the Chip Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.
After the Chip Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read Mode.
The Chip Erase Command sets all of the bits in unprotected blocks of the memory to '1'. All previous data is lost.

## Block Erase Command

The Block Erase command can be used to erase a list of one or more blocks. Six Bus Write operations are required to select the first block in the list. Each additional block in the list can be selected by repeating the sixth Bus Write operation using the address of the additional block. The Block Erase operation starts the Program/Erase Controller about $50 \mu \mathrm{~s}$ after the last Bus Write operation. Once the Program/Erase Controller starts it is not possible to select any more blocks. Each additional block must therefore be selected within $50 \mu$ s of the lowest address block. The $50 \mu$ s timer restarts when an additional block is selected. The Status Register can be read after the sixth Bus Write operation. See the Status Register section for details on how to identify if the Program/Erase Controller has started the Block Erase operation.
If any selected blocks are protected then these are ignored and all the other selected blocks are erased. If all of the selected blocks are protected the Block Erase operation appears to start but will
terminate within about $100 \mu \mathrm{~s}$, leaving the data unchanged. No error condition is given when protected blocks are ignored.
During the Block Erase operation the memory will ignore all commands except the Erase Suspend command. Typical block erase times are given in Table 4. All Bus Read operations during the Block Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.
After the Block Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.
The Block Erase Command sets all of the bits in the unprotected selected blocks to '1'. All previous data in the selected blocks is lost.

## Erase Suspend Command

The Erase Suspend Command may be used to temporarily suspend a Block Erase operation and return the memory to Read mode. The command requires one Bus Write operation.
The Program/Erase Controller will suspend within the Erase Suspend Latency time of the Erase Suspend Command being issued. Once the Program/ Erase Controller has stopped the memory will be set to Read mode and the Erase will be suspended. If the Erase Suspend command is issued during the period when the memory is waiting for an additional block (before the Program/Erase Controller starts) then the Erase is suspended immediately and will start immediately when the Erase Resume Command is issued. It is not possible to select any further blocks to erase after the Erase Resume.
During Erase Suspend it is possible to Read and Program cells in blocks that are not being erased; both Read and Program operations behave as normal on these blocks. If any attempt is made to program in a protected block or in the suspended block then the Program command is ignored and the data remains unchanged. The Status Register is not read and no error condition is given. Reading from blocks that are being erased will output the Status Register.

It is also possible to issue the Auto Select, Read CFI Query and Unlock Bypass commands during an Erase Suspend. The Read/Reset command must be issued to return the device to Read Array mode before the Resume command will be accepted.

## Erase Resume Command

The Erase Resume command must be used to restart the Program/Erase Controller after an Erase Suspend. The device must be in Read Array mode before the Resume command will be accepted. An erase can be suspended and resumed more than once.

## Enter Extended Block Command

The device has an extra 32 KWord block (Extended Block) that can only be accessed using the Enter Extended Block command. Three Bus write cycles are required to issue the Extended Block command. Once the command has been issued the device enters Extended Block mode where all Bus Read or Write operations to the Boot Block addresses access the Extended Block. The Extended Block (with the same address as the Boot Blocks) cannot be erased, and can be treated as one-time programmable (OTP) memory. In Extended Block mode the Boot Blocks are not accessible.
To exit from the Extended Block mode the Exit Extended Block command must be issued.
The Extended Block can be protected, however once protected the protection cannot be undone.

## Exit Extended Block Command

The Exit Extended Block command is used to exit from the Extended Block mode and return the device to Read mode. Four Bus Write operations are required to issue the command.
Block Protect and Chip Unprotect Commands
Groups of blocks can be protected against accidental Program or Erase. The whole chip can be unprotected to allow the data inside the blocks to be changed.
Block Protect and Chip Unprotect operations are described in Appendix D.

## M29W641DH, M9W641DL, M29W641DU

Table 3. Commands

| Command |  | Bus Write Operations |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 1st |  | 2nd |  | 3rd |  | 4th |  | 5th |  | 6th |  |
|  |  | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data |

Note: X Don't Care, PA Program Address, PD Program Data, BA Any address in the Block. All values in the table are in hexadecimal.
Table 4. Program, Erase Times and Program, Erase Endurance Cycles

| Parameter | Min | $\operatorname{Typ}^{(1,2)}$ | Max $^{(2)}$ | Unit |
| :--- | :---: | :---: | :---: | :---: |
| Chip Erase |  | 80 | $400^{(3)}$ | s |
| Block Erase (32 KWords) |  | 0.8 | $6^{(4)}$ | s |
| Erase Suspend Latency Time |  |  | $50^{(4)}$ | $\mu \mathrm{s}$ |
| Program (Word) |  | 10 | $200^{(3)}$ | $\mu \mathrm{s}$ |
| Double Word Program |  | 10 | $200^{(3)}$ | $\mu \mathrm{s}$ |
| Chip Program (Word by Word) |  | 40 | $200^{(3)}$ | s |
| Chip Program (Double Word) |  | 20 | $100^{(3)}$ | s |
| Program/Erase Cycles (per Block) | 100,000 |  |  | cycles |
| Data Retention | 20 |  |  | years |

Note: 1. Typical values measured at room temperature and nominal voltages.
2. Sampled, but not $100 \%$ tested.
3. Maximum value measured at worst case conditions for both temperature and $\mathrm{V}_{\mathrm{CC}}$ after 100,00 program/erase cycles
4. Maximum value measured at worst case conditions for both temperature and $\mathrm{V}_{\mathrm{CC}}$.

## STATUS REGISTER

Bus Read operations from any address always read the Status Register during Program and Erase operations. It is also read during Erase Suspend when an address within a block being erased is accessed.
The bits in the Status Register are summarized in Table 5, Status Register Bits.
Data Polling Bit (DQ7). The Data Polling Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Data Polling Bit is output on DQ7 when the Status Register is read.
During Program operations the Data Polling Bit outputs the complement of the bit being programmed to DQ7. After successful completion of the Program operation the memory returns to Read mode and Bus Read operations from the address just programmed output DQ7, not its complement.
During Erase operations the Data Polling Bit outputs ' 0 ', the complement of the erased state of DQ7. After successful completion of the Erase operation the memory returns to Read Mode.
In Erase Suspend mode the Data Polling Bit will output a '1' during a Bus Read operation within a block being erased. The Data Polling Bit will change from a ' 0 ' to a ' 1 ' when the Program/Erase Controller has suspended the Erase operation.
Figure 5, Data Polling Flowchart, gives an example of how to use the Data Polling Bit. A Valid Address is the address being programmed or an address within the block being erased.
Toggle Bit (DQ6). The Toggle Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Toggle Bit is output on DQ6 when the Status Register is read.
During Program and Erase operations the Toggle Bit changes from '0' to ' 1 ' to '0', etc., with successive Bus Read operations at any address. After successful completion of the operation the memory returns to Read mode.
During Erase Suspend mode the Toggle Bit will output when addressing a cell within a block being erased. The Toggle Bit will stop toggling when the Program/Erase Controller has suspended the Erase operation.
Figure 6, Data Toggle Flowchart, gives an example of how to use the Data Toggle Bit.

Error Bit (DQ5). The Error Bit can be used to identify errors detected by the Program/Erase Controller. The Error Bit is set to '1' when a Program, Block Erase or Chip Erase operation fails to write the correct data to the memory. If the Error Bit is set a Read/Reset command must be issued before other commands are issued. The Error bit is output on DQ5 when the Status Register is read.
Note that the Program command cannot change a bit set to '0' back to '1' and attempting to do so will set DQ5 to ' 1 '. A Bus Read operation to that address will show the bit is still ' 0 '. One of the Erase commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.
Erase Timer Bit (DQ3). The Erase Timer Bit can be used to identify the start of Program/Erase Controller operation during a Block Erase command. Once the Program/Erase Controller starts erasing the Erase Timer Bit is set to '1'. Before the Program/Erase Controller starts the Erase Timer Bit is set to ' 0 ' and additional blocks to be erased may be written to the Command Interface. The Erase Timer Bit is output on DQ3 when the Status Register is read.
Alternative Toggle Bit (DQ2). The Alternative Toggle Bit can be used to monitor the Program/ Erase controller during Erase operations. The Alternative Toggle Bit is output on DQ2 when the Status Register is read.
During Chip Erase and Block Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with successive Bus Read operations from addresses within the blocks being erased. A protected block is treated the same as a block not being erased. Once the operation completes the memory returns to Read mode.
During Erase Suspend the Alternative Toggle Bit changes from ' 0 ' to ' 1 ' to ' 0 ', etc. with successive Bus Read operations from addresses within the blocks being erased. Bus Read operations to addresses within blocks not being erased will output the memory cell data as if in Read mode.
After an Erase operation that causes the Error Bit to be set the Alternative Toggle Bit can be used to identify which block or blocks have caused the error. The Alternative Toggle Bit changes from '0' to ' 1 ' to '0', etc. with successive Bus Read Operations from addresses within blocks that have not erased correctly. The Alternative Toggle Bit does not change if the addressed block has erased correctly.

## M29W641DH, M9W641DL, M29W641DU

Table 5. Status Register Bits

| Operation | Address | DQ7 | DQ6 | DQ5 | DQ3 | DQ2 | $R \bar{B}^{(1)}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Program | Any Address | DQ7 | Toggle | 0 | - | - | 0 |
| Program During Erase Suspend | Any Address | DQ7 | Toggle | 0 | - | - | 0 |
| Program Error | Any Address | $\overline{\text { DQ7 }}$ | Toggle | 1 | - | - | 0 |
| Chip Erase | Any Address | 0 | Toggle | 0 | 1 | Toggle | 0 |
| Block Erase before timeout | Erasing Block | 0 | Toggle | 0 | 0 | Toggle | 0 |
|  | Non-Erasing Block | 0 | Toggle | 0 | 0 | $\begin{gathered} \text { No } \\ \text { Toggle } \end{gathered}$ | 0 |
| Block Erase | Erasing Block | 0 | Toggle | 0 | 1 | Toggle | 0 |
|  | Non-Erasing Block | 0 | Toggle | 0 | 1 | $\begin{gathered} \text { No } \\ \text { Toggle } \end{gathered}$ | 0 |
| Erase Suspend | Erasing Block | 1 | $\begin{gathered} \text { No } \\ \text { Toggle } \end{gathered}$ | 0 | - | Toggle | Hi-Z |

## MAXIMUM RATING

Stressing the device above the rating listed in the Absolute Maximum Ratings table may cause permanent damage to the device. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. These are stress ratings only and operation of the device at
these or any other conditions above those indicated in the Operating sections of this specification is not implied. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.

Table 6. Absolute Maximum Ratings

| Symbol | Parameter | Min | Max | Unit |
| :---: | :--- | :---: | :---: | :---: |
| $\mathrm{T}_{\mathrm{BIAS}}$ | Temperature Under Bias | -50 | 125 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {STG }}$ | Storage Temperature | -65 | 150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {LEAD }}$ | Lead Temperature during Soldering $^{(1)}$ |  | $260^{(2)}$ | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{V}_{\mathrm{CCQ}}$ | Input/Output Supply Voltage ${ }^{(3,4)}$ | -0.6 | 4 | $\mathrm{~V}^{2}$ |
| $\mathrm{~V}_{\mathrm{CC}}$ | Supply Voltage | -0.6 | 4 | V |
| $\mathrm{~V}_{\text {ID }}$ | Identification Voltage | -0.6 | 13.5 | V |
| $\mathrm{~V}_{\text {PP }}{ }^{(5)}$ | Program Voltage | -0.6 | 13.5 | V |

Note: 1. Compliant with the ECOPACK ${ }^{\circledR} 7191395$ specification for Lead-free soldering processes.
2. Not exceeding $250^{\circ} \mathrm{C}$ for more than 30 s , and peaking at $260^{\circ} \mathrm{C}$.
3. Minimum voltage may undershoot to -2 V during transition and for less than 20 ns during transitions.
4. Maximum voltage may overshoot to $\mathrm{V}_{\mathrm{CC}}+2 \mathrm{~V}$ during transition and for less than 20 ns during transitions.
5. $\mathrm{V}_{\mathrm{PP}}$ must not remain at 12 V for more than a total of 80 hrs .

## DC AND AC PARAMETERS

This section summarizes the operating and measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC Characteristic tables that follow are derived from tests performed under the Measure-
ment Conditions summarized in the relevant tables. Designers should check that the operating conditions in their circuit match the measurement conditions when relying on the quoted parameters.

Table 7. Operating and AC Measurement Conditions

| Parameter | M29W641D |  |  |  |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## PART NUMBERING

## Table 16. Ordering Information Scheme

| Example: |
| :--- |
| Device Type |
| M29 29 W 641 DL |
| Operating Voltage |
| $\mathrm{W}=\mathrm{V}_{\mathrm{CC}}=2.7$ to 3.6 V |
| Device Function |

641DH = 64 Mbit (x16), Uniform Block, Write Protection on highest address Block
641 DL = 64 Mbit (x16), Uniform Block, Write Protection on Lowest Address Block
641 DU $=64$ Mbit (x16), Uniform Block, No Write Protection

Speed
$90=90 \mathrm{~ns}$
$10=100 \mathrm{~ns}$
$12=120 \mathrm{~ns}$

## Package

N = TSOP48: $12 \times 20 \mathrm{~mm}$ (M29W641DH and M29W641DL only)
ZA = TFBGA63: $7 \times 11 \mathrm{~mm}, 0.80 \mathrm{~mm}$ pitch (M29W641DU only)

Temperature Range
$1=0$ to $70^{\circ} \mathrm{C}$
$6=-40$ to $85^{\circ} \mathrm{C}$

## Option

Blank = Standard Packing
T = Tape \& Reel Packing
$\mathrm{E}=$ Lead-free Package, Standard Packing
F = Lead-free Package, Tape \& Reel Packing
Note: This product is also available with the Extended Block factory locked. For further details and ordering information contact your nearest ST sales office.

Devices are shipped from the factory with the memory content bits erased to 1 . For a list of available options (Speed, Package, etc.) or for further information on any aspect of this device, please contact your nearest ST Sales Office.

## M29W641DH, M9W641DL, M29W641DU

## APPENDIX B. COMMON FLASH INTERFACE (CFI)

The Common Flash Interface is a JEDEC approved, standardized data structure that can be read from the Flash memory device. It allows a system software to query the device to determine various electrical and timing parameters, density information and functions supported by the memory. The system can interface easily with the device, enabling the software to upgrade itself when necessary.

When the CFI Query Command is issued the device enters CFI Query mode and the data structure is read from the memory. Table 18 to Table 23 show the addresses used to retrieve the data.
The CFI data structure also contains a security area where a 64 bit unique security number is written (see Table 23, Security Code Area). This area can be accessed only in Read mode by the final user. It is impossible to change the security number after it has been written by ST.

Table 18. Query Structure Overview

| Address | Sub-section Name | Description |
| :---: | :--- | :--- |
| 10 h | CFI Query Identification String | Command set ID and algorithm data offset |
| 1 Bh | System Interface Information | Device timing \& voltage information |
| 27 h | Device Geometry Definition | Flash device layout |
| 40 h | Primary Algorithm-specific Extended <br> Query table | Additional information specific to the Primary <br> Algorithm (optional) |
| 61 h | Security Code Area | 64 bit unique device number |

Note: Query data are always presented on the lowest order data outputs.

Table 19. CFI Query Identification String

| Address | Data | Description | Value |
| :---: | :---: | :--- | :---: |
| 10 h | 0051 h |  | "Q" |
| 11 h | 0052 h | Query Unique ASCII String "QRY" | "R" |
| 12 h | 0059 h |  | "Y" |
| 13 h | 0002 h | Primary Algorithm Command Set and Control Interface ID code 16 bit | AMD <br> Compatible |
| 14 h | 0000 h | ID code defining a specific algorithm | P = 40h |
| 15 h | 0040 h | Address for Primary Algorithm extended Query table (see Table 22) |  |
| 16 h | 0000 h |  | NA |
| 17 h | 0000 h | Alternate Vendor Command Set and Control Interface ID Code second <br> vendor - specified algorithm supported | NA |
| 18 h | 0000 h | 0000 h | Address for Alternate Algorithm extended Query table |
| 1 Ah | 0000 h |  |  |

Note: Query data are always presented on the lowest order data outputs (DQ7-DQ0) only. DQ8-DQ15 are '0'.

Table 20. CFI Query System Interface Information

| Address | Data | Description | Value |
| :---: | :---: | :---: | :---: |
| 1Bh | 0027h | VCC Logic Supply Minimum Program/Erase voltage bit 7 to 4BCD value in volts bit 3 to $0 B C D$ value in 100 mV | 2.7V |
| 1Ch | 0036h | VCC Logic Supply Maximum Program/Erase voltage bit 7 to 4BCD value in volts bit 3 to $0 B C D$ value in 100 mV | 3.6V |
| 1Dh | 00B5h | VPP [Programming] Supply Minimum Program/Erase voltage bit 7 to 4 HEX value in volts bit 3 to $0 B C D$ value in 100 mV | 11.5 V |
| 1Eh | 00C5h | VPP [Programming] Supply Maximum Program/Erase voltage bit 7 to 4 HEX value in volts bit 3 to $0 B C D$ value in 100 mV | 12.5 V |
| 1Fh | 0004h | Typical timeout per single word program $=2^{n} \mu \mathrm{~s}$ | $16 \mu \mathrm{~s}$ |
| 20h | 0000h | Typical timeout for minimum size write buffer program $=2^{n} \mu \mathrm{~s}$ | NA |
| 21h | 000Ah | Typical timeout per individual Block Erase $=2^{\mathrm{n}} \mathrm{ms}$ | 1s |
| 22h | 0000h | Typical timeout for full Chip Erase $=2^{\mathrm{n}} \mathrm{ms}$ | NA |
| 23h | 0004h | Maximum timeout for word program $=2^{n}$ times typical | 256 ¢s |
| 24h | 0000h | Maximum timeout for write buffer program $=2^{n}$ times typical | NA |
| 25h | 0003h | Maximum timeout per individual Block Erase $=2^{n}$ times typical | 8 s |
| 26h | 0000h | Maximum timeout for Chip Erase $=2^{n}$ times typical | NA |

## M29W641DH, M9W641DL, M29W641DU

Table 21. Device Geometry Definition

| Address | Data | Description | Value |

## APPENDIX C. EXTENDED MEMORY BLOCK

The M29W641D has an extra block, the Extended Block, that can be accessed using a dedicated command.
This Extended Block is 32 KWords. It is used as a security block (to provide a permanent security identification number) or to store additional information.
The Extended Block is either Factory Locked or Customer Lockable, its status is indicated by bit DQ7. This bit is permanently set to either ' 1 ' or ' 0 ' at the factory and cannot be changed. When set to ' 1 ', it indicates that the device is factory locked and the Extended Block is protected. When set to ' 0 ', it indicates that the device is customer lockable and the Extended Block is unprotected. Bit DQ7 being permanently locked to either ' 1 ' or ' 0 ' is another security feature which ensures that a customer lockable device cannot be used instead of a factory locked one.
Bit DQ7 is the most significant bit in the Extended Block Verify Code and a specific procedure must be followed to read it. See "Extended Memory Block Verify Code" in Table 2, Bus Operations, for details of how to read bit DQ7.
The Extended Block can only be accessed when the device is in Extended Block mode. For details of how the Extended Block mode is entered and exited, refer to the Enter Extended Block Command and Exit Extended Block Command paragraphs, and to Table 3, "Commands".

## Factory Locked Extended Block

In devices where the Extended Block is factory locked, the Security Identification Number is writ-
ten to the Extended Block address space (see Table 24, Extended Block Address and Data) in the factory. The DQ7 bit is set to ' 1 ' and the Extended Block cannot be unprotected.

## Customer Lockable Extended Block

A device where the Extended Block is customer lockable is delivered with the DQ7 bit set to ' 0 ' and the Extended Block unprotected. It is up to the customer to program and protect the Extended Block but care must be taken because the protection of the Extended Block is not reversible.
There are two ways of protecting the Extended Block:
■ Issue the Enter Extended Block command to place the device in Extended Block mode, then use the In-System Technique with RP either at $\mathrm{V}_{I H}$ or at $\mathrm{V}_{\text {ID }}$ (refer to Appendix D, InSystem Technique and to the corresponding flowcharts, Figures 18 and 19, for a detailed explanation of the technique).

- Issue the Enter Extended Block command to place the device in Extended Block mode, then use the Programmer Technique (refer to Appendix D, Programmer Technique and to the corresponding flowcharts, Figures 16 and 17, for a detailed explanation of the technique).
Once the Extended Block is programmed and protected, the Exit Extended Block command must be issued to exit the Extended Block mode and return the device to Read mode.

Table 24. Extended Block Address and Data

| Device | Address ${ }^{(1)}$ | Data |  |
| :---: | :---: | :---: | :---: |
|  | $\mathbf{x 1 6}$ | Factory Locked | Customer Lockable |
| M29W641D | $000000 \mathrm{~h}-000007 \mathrm{~h}$ | Security Identification Number | Determined by Customer |
|  | $000008 \mathrm{~h}-007 \mathrm{FFFh}$ | Unavailable |  |

Note: 1. See Table 17, Block Addresses.

## APPENDIX D. BLOCK PROTECTION

Block protection can be used to prevent any operation from modifying the data stored in the memory. Once protected, Program and Erase operations within the protected group fail to change the data.
There are three techniques that can be used to control Block Protection, these are the Programmer technique, the In-System technique and Temporary Unprotection. Temporary Unprotection is controlled by the Reset/Block Temporary Unprotection pin, RP; this is described in the Signal Descriptions section.

## Programmer Technique

The Programmer technique uses high ( $\mathrm{V}_{\text {ID }}$ ) voltage levels on some of the bus pins. These cannot be achieved using a standard microprocessor bus, therefore the technique is recommended only for use in Programming Equipment.
To protect a group of blocks follow the flowchart in Figure 16, Programmer Equipment Group Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the groups first, then all groups can be unprotected at the same time. To unprotect the chip follow Figure 17, Programmer Equipment Chip Unprotect Flowchart. Table 25, Programmer Technique Bus Operations, gives a summary of each operation.
The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do
not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

## In-System Technique

The In-System technique requires a high voltage level on the Reset/Blocks Temporary Unprotect $\mathrm{pin}, \overline{\mathrm{RP}}^{(1)}$. This can be achieved without violating the maximum ratings of the components on the microprocessor bus, therefore this technique is suitable for use after the memory has been fitted to the system.
To protect a group of blocks follow the flowchart in Figure 18, In-System Equipment Group Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the groups first, then all the groups can be unprotected at the same time. To unprotect the chip follow Figure 19, In-System Equipment Chip Unprotect Flowchart.
The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not allow the microprocessor to service interrupts that will upset the timing and do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.
Note: 1. $\overline{\mathrm{RP}}$ can be either at $\mathrm{V}_{\mathrm{IH}}$ or at $\mathrm{V}_{I D}$ when using the In-System Technique to protect the Extended Block.

Table 25. Programmer Technique Bus Operations

| Operation | $\overline{\mathrm{E}}$ | $\overline{\mathbf{G}}$ | $\overline{\text { W }}$ | Address Inputs A0-A21 | Data Inputs/Outputs DQ15-DQ0 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Block (Group) Protect ${ }^{(1)}$ | VIL | VID | VIL Pulse | $\begin{gathered} \mathrm{A} 9=\mathrm{V}_{\mathrm{ID}}, \mathrm{~A} 12-\mathrm{A} 21 \text { Block Address } \\ \text { Others }=\mathrm{X} \end{gathered}$ | X |
| Chip Unprotect | $V_{\text {ID }}$ | $V_{\text {ID }}$ | $\mathrm{V}_{\text {IL }}$ Pulse | $\begin{gathered} \mathrm{A} 9=\mathrm{V}_{\mathrm{ID}}, \mathrm{~A} 12=\mathrm{V}_{\mathrm{IH}}, \mathrm{~A} 15=\mathrm{V}_{\mathrm{IH}} \\ \text { Others }=\mathrm{X} \end{gathered}$ | X |
| Block (Group) Protection Verify | VIL | VIL | $\mathrm{V}_{\mathrm{IH}}$ | $\begin{gathered} \mathrm{A} 0=\mathrm{V}_{\mathrm{IL}}, \mathrm{~A} 1=\mathrm{V}_{\mathrm{IH}}, \mathrm{~A} 6=\mathrm{V}_{\mathrm{IL}}, \mathrm{~A} 9=\mathrm{V}_{\mathrm{ID}}, \\ \text { A12-A21 Block Address } \\ \text { Others }=\mathrm{X} \end{gathered}$ | $\begin{aligned} & \text { Pass }=\mathrm{XX01h} \\ & \text { Retry }=\text { XX00h } \end{aligned}$ |
| Block (Group) Unprotection Verify | VIL | VIL | $\mathrm{V}_{\mathrm{IH}}$ | $\begin{gathered} \mathrm{A} 0=\mathrm{V}_{\mathrm{IL}}, \mathrm{~A} 1=\mathrm{V}_{\mathrm{IH}}, \mathrm{~A} 6=\mathrm{V}_{\mathrm{IH}}, \mathrm{~A} 9=\mathrm{V}_{\mathrm{ID}}, \\ \mathrm{~A} 12-\mathrm{A} 1 \text { Block Address } \\ \text { Others }=\mathrm{X} \end{gathered}$ | $\begin{aligned} & \text { Retry }=\text { XX01h } \\ & \text { Pass }=\text { XX00h } \end{aligned}$ |

Note: 1. Block Protection Groups are shown in Appendix A, Tables 17.

Figure 16. Programmer Equipment Group Protect Flowchart

Figure 17. Programmer Equipment Chip Unprotect Flowchart

Figure 18. In-System Equipment Group Protect Flowchart

Note: 1. Block Protection Groups are shown in Appendix D, Table 17.
2. $\overline{\mathrm{RP}}$ can be either at $\mathrm{V}_{\mathrm{IH}}$ or at $\mathrm{V}_{\text {ID }}$ when using the In-System Technique to protect the Extended Block.
