

High-Integration 16-Bit Microprocessor

SAB 80186

SAB 80186 8 MHz

- Integrated feature set
 - enhanced SAB 8086-2 CPU
 - clock generator
 - 2 independent high-speed DMA channels
 - programmable interrupt controller
 - 3 programmable 16-bit timers
 - programmable memory and peripheral chip-select logic
 - programmable wait state generator
 - local bus controller
- High-performance processor
 - twice the performance of the standard SAB 8086 at 8 MHz
 - 4 Mbyte/s bus bandwidth interface at 8 MHz

SAB 80186-1 10 MHz

- Direct addressing capability to 1 Mbyte of memory
- Completely object-code compatible with all existing SAB 8086/8088 software
 - 10 new instruction types
- Optional numerical processor extension
- Compatible with the bus support components SAB 8282A/8283A/8286A/8287A and SAB 8288A/8289
- Compatible with industry standard 80186 processor
- Available in 10 MHz (SAB 80186-1) and 8 MHz (SAB 80186) versions

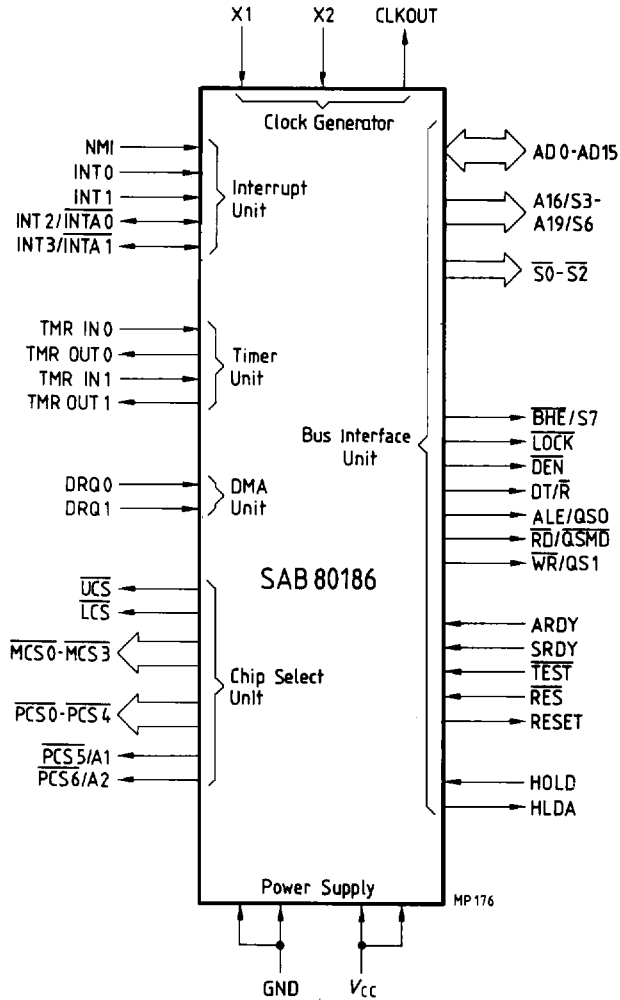

The SAB 80186 is a highly integrated 16-bit microprocessor implemented in +5V advanced Siemens MYMOS technology. It effectively combines 15 to 20 of the most common SAB 8086 system components onto one chip. The 8 MHz SAB 80186 provides twice the throughput of the standard 5 MHz SAB 8086. The SAB 80186 is

upward-compatible with SAB 8086 and SAB 8088 software, and adds 10 new instruction types to the existing set. The SAB 80186 comes in a 68-pin plastic leaded chip carrier (PL-CC-68) package and requires single +5V power supply.

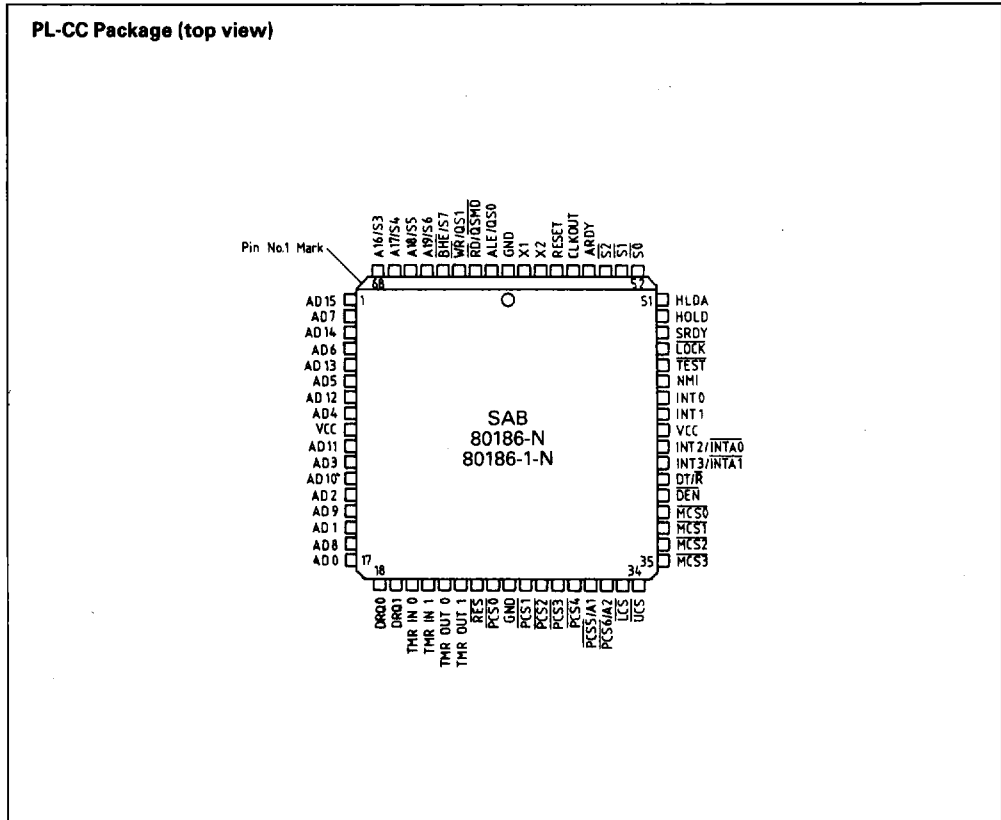

Pin Names

AD0–AD15	Address/Data Bus
A16/S3–A19/S6	Address Bus/Status Lines
S0–S2	Status Lines
BHE/S7	Bus High Enable/Status Line
LOCK	Bus Lock
DEN	Data Enable
DT/R	Data Transmit/Receive
ALE/QS0	Address Latch Enable/Queue Status
RD/QSMD	Read Strobe/Queue Status Mode
WR/QS1	Write Strobe/Queue Status
ARDY	Asynchronous Ready
SRDY	Synchronous Ready
TEST	Test Line
RES	Reset Input
RESET	Reset Output
HOLD	Hold Request
HLDA	Hold Acknowledge
NMI	Non-Maskable Interrupt
INT0, INT1	Interrupt Request
INT2/INTA0	Interrupt Request/Acknowledge
INT3/INTA1	Interrupt Request/Acknowledge
TMR IN0/TMR OUT0	Timer 0 Input/Output
TMR IN1/TMR OUT1	Timer 1 Input/Output
DRQ0, DRQ1	Data Request
UCS, LCS	Upper/Lower Chip Select
MCS0–MCS3	Memory Chip Select
PCS0–PCS4	Peripheral Chip Select
PCS5/A1, PCS6/A2	Peripheral Chip Select/Address
VCC	Power Supply (+5V)
GND	Ground (0V)

Logic Symbol

Pin Configuration

Pin Definitions and Functions

Symbol	Pin	Input (I) Output (O)	Function
AD15–AD0	10–17, 1–8	I/O	ADDRESS/DATA BUS (0 TO 15) These signals constitute the time-multiplexed memory or I/O address (T1) and data (T2, T3, TW, and T4) bus. The bus is active high. A0 is analogous to $\overline{\text{BHE}}$ for the lower byte of the data bus, pins D7 through D0. It is low during T1 when a byte is to be transferred onto the lower portion of the bus in memory or I/O operations.
DRQ0 DRQ1	18 19	I I	DMA REQUEST Is driven high by an external device when it desires that a DMA channel (channel 0 or 1) performs a transfer. These signals are active high, level-triggered, and internally synchronized.
TMR IN 0, TMR IN 1	20 21	I I	TIMER INPUTS Are used either as clock or control signals, depending upon the programmed timer mode. These inputs are active high (or low-to-high transitions are counted) and internally synchronized.
TMR OUT 0, TMR OUT 1	22 23	O O	TIMER OUTPUTS Are used to provide single pulse or continuous waveform generation, depending upon the timer mode selected.
$\overline{\text{RES}}$	24	I	SYSTEM RESET Causes the SAB 80186 to immediately terminate its present activity, clear the internal logic, and enter a dormant state. This signal may be asynchronous to the SAB 80186 clock. The SAB 80186 begins fetching instructions approximately 7 clock cycles after $\overline{\text{RES}}$ is returned high. $\overline{\text{RES}}$ is required to be low for greater than 4 clock cycles and is internally synchronized. For proper initialization, the low-to-high transition of $\overline{\text{RES}}$ must occur no sooner than 50 microseconds after power up. This input is provided with a Schmitt trigger to facilitate power-on $\overline{\text{RES}}$ generation via an RC network. When $\overline{\text{RES}}$ occurs, the SAB 80186 will drive the status lines to an inactive level for one clock, and then tristate them.
$\overline{\text{PCS0}}$ $\overline{\text{PCS1}}\text{--}4$	25 27, 28, 29, 30	O O	PERIPHERAL CHIP SELECT 0 TO 4 These signals are active low when a reference is made to the defined peripheral area (64 Kbyte I/O space). These lines are not tristated during bus hold. The address ranges activating $\overline{\text{PCS0}}\text{--}4$ are software-programmable.
$\overline{\text{PCS5}}/\text{A1}$	31	O	PERIPHERAL CHIP SELECT 5/LATCHED A1 May be programmed to provide a sixth peripheral chip select, or to provide an internally latched A1 signal. The address range activating $\overline{\text{PCS5}}$ is software-programmable. When programmed to provide latched A1, rather than $\overline{\text{PCS5}}$, this pin will retain the previously latched value of A1 during a bus HOLD. A1 is active high.
$\overline{\text{PCS6}}/\text{A2}$	32	O	PERIPHERAL CHIP SELECT 6/LATCHED A2 May be programmed to provide a seventh peripheral chip select, or to provide an internally latched A2 signal. The address range activating $\overline{\text{PCS6}}$ is software-programmable. When programmed to provide latched A2, rather than $\overline{\text{PCS6}}$, this pin will retain the previously latched value of A2 during a bus HOLD. A2 is active high.

Pin Definitions and Functions (cont'd)

Symbol	Pin	Input (I) Output (O)	Function
$\overline{\text{LCS}}$	33	O	LOWER MEMORY CHIP SELECT Is active low whenever a memory reference is made to the defined lower portion (1 K to 256 K) of memory. This line is not tristated during bus HOLD. The address range activating $\overline{\text{LCS}}$ is software-programmable.
$\overline{\text{UCS}}$	34	O	UPPER MEMORY CHIP SELECT Is an active low output whenever a memory reference is made to the defined upper portion (1 K to 256 K block) of memory. This line is not tristated during bus HOLD. The address range activating $\overline{\text{UCS}}$ is software-programmable.
$\overline{\text{MCS0-3}}$	38, 37, 36, 35	O	MIDRANGE MEMORY CHIP SELECT 0 TO 3 These signals are active low when a memory reference is made to the defined midrange portion of memory (8 K to 512 K). These lines are not tristated during bus HOLD. The address ranges activating $\overline{\text{MCS0-3}}$ are software-programmable.
$\overline{\text{DEN}}$	39	O	DATA ENABLE Is provided as an SAB 8286A/8287A data bus transceiver output enable. $\overline{\text{DEN}}$ is active low during each memory and I/O access. $\overline{\text{DEN}}$ is high whenever $\text{DT}/\overline{\text{R}}$ changes its state.
$\text{DT}/\overline{\text{R}}$	40	O	DATA TRANSMIT/RECEIVE Controls the direction of data flow through the external SAB 8286A/8287A data bus transceiver. When low data is transferred to the SAB 80186. When high the SAB 80186 places write data on the data bus.
$\text{INT0}/\text{INT1}$, $\text{INT2}/\text{INTA0}$ $\text{INT3}/\text{INTA1}$	45, 44 42 41	I I/O I/O	MASKABLE INTERRUPT REQUEST Can be requested by strobing one of these pins. When configured as inputs, these pins are active high. Interrupt requests are synchronized internally. INT2 and INT3 may be configured via software to provide active low interrupt-acknowledge output signals. All interrupt inputs may be configured via software to be either edge or level-triggered. To ensure recognition, all interrupt requests must remain active until the interrupt is acknowledged. When iRMX mode is selected, the function of these pins changes (see Interrupt Controller section of this data sheet).
NMI	46	I	NON-MASKABLE INTERRUPT Is an edge-triggered input which causes a type 2 interrupt. NMI is not maskable internally. A transition from low to high initiates the interrupt at the next instruction boundary. NMI is latched internally. An NMI duration of one clock or more will guarantee service. This input is internally synchronized.
$\overline{\text{TEST}}$	47	I	TEST Is examined by the WAIT instruction. If the $\overline{\text{TEST}}$ input is high when "WAIT" execution begins, instruction execution will suspend. $\overline{\text{TEST}}$ will be resampled until it goes low, at which time execution will be resumed. If interrupts are enabled while the SAB 80186 is waiting for $\overline{\text{TEST}}$, interrupts will be serviced. This input is synchronized internally.

Pin Definitions and Functions (cont'd)

Symbol	Pin	Input (I) Output (O)	Function																																				
LOCK	48	O	<p>LOCK</p> <p>This output indicates that other system bus masters are not to gain control of the system bus while LOCK is active low. The LOCK signal is requested by the LOCK prefix instruction and is activated at the beginning of the first data cycle associated with the instruction following the LOCK prefix. It remains active until the completion of the instruction following the LOCK prefix. No pre-fetches will occur while LOCK is asserted. LOCK is active low, is driven high for one clock during reset, and then tristated.</p>																																				
SRDY	49	I	<p>SYNCHRONOUS READY</p> <p>Must be synchronized externally to the SAB 80186. The use of SRDY provides a relaxed system-timing specification on the ready input. This is accomplished by eliminating the one-half clock cycle which is required for internally resolving the signal level when using the ARDY input. This line is active high. If this line is connected to VCC no wait states are inserted. Asynchronous ready (ARDY) or synchronous ready (SRDY) must be active before a bus cycle is terminated. If unused, this line should be tied low.</p>																																				
HOLD HLDA	50 51	I O	<p>HOLD/HOLD ACKNOWLEDGE</p> <p>Indicates that another bus master is requesting the local bus. The HOLD input is active high. HOLD may be asynchronous with respect to the SAB 80186 clock. The SAB 80186 will issue a HLDA (high) in response to a HOLD request at the end of T4 or T1. Simultaneous with issuing HLDA, the SAB 80186 will tristate the local bus and control lines. After HOLD is detected as being low, the SAB 80186 will lower HLDA. When the SAB 80186 needs to run another bus cycle, it will again drive the local bus and control lines.</p>																																				
S0, S1, S2	52-54	O	<p>BUS CYCLE STATUS</p> <p>S0 to S2 are encoded to provide bus transaction information: SAB 80186 Bus Cycle Status Information</p> <table border="1"> <thead> <tr> <th>S2</th> <th>S1</th> <th>S0</th> <th>Bus Cycle Initiated</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>Interrupt Acknowledge</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>Read I/O</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>Write I/O</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>Halt</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>Instruction Fetch</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>Read Data from Memory</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>Write Data to Memory</td> </tr> <tr> <td>1</td> <td>1</td> <td>1</td> <td>Passive (no bus cycle)</td> </tr> </tbody> </table> <p>The status pins are tristated during "HOLD." S2 may be used as a logical M/I\bar{O} indicator, and S1 as a DT/\bar{R} indicator. The status lines are driven high for one clock during reset, and then tristated until a bus cycle begins.</p>	S2	S1	S0	Bus Cycle Initiated	0	0	0	Interrupt Acknowledge	0	0	1	Read I/O	0	1	0	Write I/O	0	1	1	Halt	1	0	0	Instruction Fetch	1	0	1	Read Data from Memory	1	1	0	Write Data to Memory	1	1	1	Passive (no bus cycle)

1	1	1	Passive (no bus cycle)																																				

Pin Definitions and Functions (cont'd)

Symbol	Pin	Input (I) Output (O)	Function
ARDY	55	I	ASYNCHRONOUS READY Informs the SAB 80186 that the addressed memory space or I/O device will complete a data transfer. The ARDY input pin will accept an asynchronous input and is active high. Only the rising edge is internally synchronized by the SAB 80186. This means that the falling edge of ARDY must be synchronized to the SAB 80186 clock. If connected to VCC no wait states are inserted. Asynchronous ready (ARDY) or synchronous ready (SRDY) must be active to terminate a bus cycle. If unused, this line should be tied low.
CLKOUT	56	O	CLOCK OUTPUT Provides the system with a 50% duty cycle waveform. All device pin timings are specified relative in CLKOUT.
RESET	57	O	RESET This output indicates that the SAB 80186 CPU is being reset, and can be used as a system reset. It is active high, synchronized with the processor clock, and lasts an integer number of clock periods corresponding to the length of the \overline{RES} signal.
X1, X2	59, 58	I	CRYSTAL INPUTS X1 and X2 provide an external connection for a fundamental-mode parallel resonant crystal for the internal crystal oscillator. X1 can interface to an external clock instead of a crystal. In this case, minimize the capacitance on X2 or drive X2 with complemented X1. The input or oscillator frequency is internally divided by two to generate the clock signal (CLKOUT).
ALE/QS0	61	O	ADDRESS LATCH ENABLE/QUEUE STATUS 0 Is provided by the SAB 80186 to latch the address into the SAB 8282A/8283A address latches. ALE is active high. Addresses are guaranteed to be valid on the trailing edge of ALE. The ALE rising edge is generated off the rising edge of the CLKOUT immediately preceding T1 of the associated bus cycle, effectively half a clock cycle earlier than in the standard SAB 8086. The trailing edge is generated off the CLKOUT rising edge in T1 like in the SAB 8086. Note that ALE is never tristated.
\overline{RD} /QSMD	62	O	READY STROBE Indicates that the SAB 80186 is performing a memory or I/O read cycle. \overline{RD} is active low for T2, T3 and TW of any read cycle. It is guaranteed not to go low in T2 until after the address bus is tristated. \overline{RD} is active low and tristated during "HOLD". \overline{RD} is driven high for one clock during reset, and then the output driver is tristated. A weak internal pullup mechanism on the \overline{RD} line holds it high when the line is not driven. During reset, the pin is sampled to determine whether the SAB 80186 should provide ALE, \overline{WR} and RD, or if the queue status should be provided. \overline{RD} should be connected to GND to provide queue status data.

Pin Definitions and Functions (cont'd)

WR/QS1	63	O	<p>WRITE STROBE/QUEUE STATUS 1 Indicates that the data on the bus is to be written into a memory or an I/O device. WR is active for T2, T3, and TW of any write cycle. It is active low and tristated during "HOLD." It is driven high for one clock during reset, and then tristated. When the SAB 80186 is in queue status mode, the ALE/QS0 and WR/QS1 pins provide information about processor/instruction queue interaction.</p> <table border="1"> <thead> <tr> <th>QS1</th> <th>QS0</th> <th>Queue Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>No Queue Operation</td> </tr> <tr> <td>0</td> <td>1</td> <td>First Op Code Byte Fetched from the Queue</td> </tr> <tr> <td>1</td> <td>1</td> <td>Subsequent Byte Fetched from the Queue</td> </tr> <tr> <td>1</td> <td>0</td> <td>Empty the Queue</td> </tr> </tbody> </table>	QS1	QS0	Queue Operation	0	0	No Queue Operation	0	1	First Op Code Byte Fetched from the Queue	1	1	Subsequent Byte Fetched from the Queue	1	0	Empty the Queue
QS1	QS0	Queue Operation																
0	0	No Queue Operation																
0	1	First Op Code Byte Fetched from the Queue																
1	1	Subsequent Byte Fetched from the Queue																
1	0	Empty the Queue																
BHE/S7	64	O	<p>BUS HIGH ENABLE During T1 this signal should be used to determine if data is to be enabled onto the most significant half of the data bus pins D15 to D8. BHE is low during T1 for read, write, and interrupt acknowledge cycles when a byte is to be transferred on the higher half of the bus. The S7 status information is available during T2, T3, and T4. S7 is logically equivalent to BHE. The signal is active low, and is tristated off during bus HOLD.</p> <p style="text-align: center;">BHE and A0 Encodings</p> <table border="1"> <thead> <tr> <th>BHE Value</th> <th>A0 Value</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Word Transfer</td> </tr> <tr> <td>0</td> <td>1</td> <td>Byte Transfer on Upper Half of Data Bus (D15 to D8)</td> </tr> <tr> <td>1</td> <td>0</td> <td>Byte Transfer on Lower Half of Data Bus (D7 to D0)</td> </tr> <tr> <td>1</td> <td>1</td> <td>Reserved</td> </tr> </tbody> </table>	BHE Value	A0 Value	Function	0	0	Word Transfer	0	1	Byte Transfer on Upper Half of Data Bus (D15 to D8)	1	0	Byte Transfer on Lower Half of Data Bus (D7 to D0)	1	1	Reserved

Functional Description

The SAB 8086, 8088, 80186, 80188 and 80286 families all contain the same basic set of registers, instructions, and addressing modes. The SAB 80186 processor is upward-compatible with the SAB 8086 and SAB 8088 CPUs.

Register Set

The SAB 80186 base architecture has fourteen registers. These registers are grouped into the following categories.

General registers

Eight 16-bit general-purpose registers may be used to contain arithmetic and logical operands. Four of these (AX, BX, CX, and DX) can be used as 16-bit registers or split into pairs of separate 8-bit registers.

Segment registers

Four 16-bit special-purpose registers select, at any time given, the segments of memory that are immediately addressable for code, stack, and data.

Base and index registers

Four of the general-purpose registers may also be used to determine offset addresses of operands in memory. These registers may contain base addresses or indexes to particular locations within a segment. The addressing mode selects the specific registers for operand and address calculations.

Status and control registers

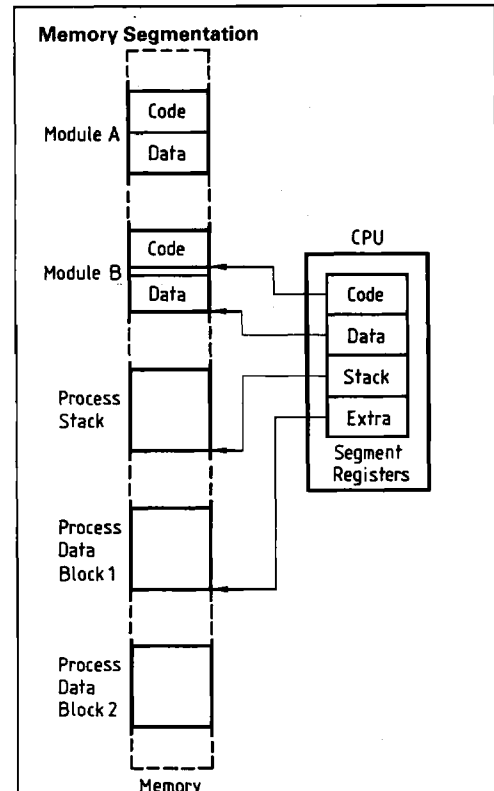

Two 16-bit special-purpose registers record or alter certain aspects of the SAB 80186 processor state. These are the instruction pointer register, which contains the offset address of the next sequential instruction to be executed, and the status word register, which contains status and control flag bits.

Memory Organization

Memory is organized in sets of segments. Each segment is a linear contiguous sequence of up to 64 K (2^{16}) 8-bit bytes. Memory is addressed using a two-component address (a pointer) that consists of a 16-bit base segment and a 16-bit offset. The 16-bit base values are contained in one of four internal segment registers (code, data, stack, extra). The physical address is calculated by shifting the base value left by four bits and adding the 16-bit offset value to yield a 20-bit physical address. This allows for a 1 Mbyte physical address size.

All instructions that address operands in memory must specify the base segment and the 16-bit offset value. For speed and compact instruction encoding, the segment register used for physical address generation is implied by the addressing mode used. These rules follow the way programs are written as independent modules that require areas for code and data, a stack, and access to external data areas.

Special segment override instruction prefixes allow the implicit segment register selection rules to be overridden for special cases. The stack, data, and extra segments may coincide for simple programs.

I/O Space

The I/O space consists of 64 K 8-bit or 32 K 16-bit ports. Separate instructions address the I/O space with either an 8-bit port address, specified in the instruction, or a 16-bit port address in the DX register. 8-bit port addresses are zero-extended such that A15 to A8 are low I/O port addresses 00F8(H) through 00FF(H) are reserved.

Interrupts

An interrupt transfers execution to a new program location. The old program address (CS:IP) and machine state (status word) are saved on the stack to allow resumption of the interrupted program. Interrupts fall into three classes: hardware-initiated, INT instructions, and instruction exceptions. Hardware-initiated interrupts occur in response to an external input and are classified as non-maskable or maskable.

Interrupt Sources

The SAB 80186 can service interrupts generated by software or hardware. The software interrupts are generated by specific instructions (INT, ESC, unused OP, etc.) or the results of conditions specified by instructions (array bounds check, INTO, DIV, IDIV, etc.). All interrupt sources are serviced by an indirect call through an element of a vector table. This vector table is indexed by using the interrupt vector type, multiplied by four. All hardware-generated interrupts are sampled at the end of each instruction. Thus, the software interrupts will begin service first. Once the service routine is entered and interrupts are enabled, any hardware source of sufficient priority can interrupt the service routine in progress.

Interrupt Vector Table

Interrupt Name	Vector Type	Default Priority ⁵⁾	Related Instructions
Divide Error Exception	0	1 ¹⁾	DIV, IDIV
Single-Step Interrupt	1	12 ²⁾ 2	All
NMI	2	1	All
Breakpoint Interrupt	3	1 ¹⁾	INT
INT0 Detected	4	1 ¹⁾	INT0
Overflow Exception			
Array Bounds Exception	5	1 ¹⁾	BOUND
Unused Op Code Exception	6	1 ¹⁾	Undefined Op Codes
ESC Op Code Exception	7	1 ¹⁾³⁾	ESC Op Codes
Timer 0 Interrupt	8	2A ⁴⁾	
Timer 1 Interrupt	18	2B ⁴⁾	
Timer 2 Interrupt	19	2C ⁴⁾	
Reserved	9	3	
DMA 0 Interrupt	10	4	
DMA 1 Interrupt	11	5	
INT0 Interrupt	12	6	
INT1 Interrupt	13	7	
INT2 Interrupt	14	8	
INT3 Interrupt	15	9	

¹⁾ These are generated as the result of an instruction execution.

²⁾ This is handled as in the SAB 8086.

³⁾ An escape op code will cause a trap only if the proper bit is set in the peripheral control block relocation register.

⁴⁾ All three timers constitute one source of request to the interrupt controller. The timer interrupts all have the same default priority level with respect to all other interrupt sources. However, they have a defined priority ordering amongst themselves. (Priority 2A is higher priority than 2B.) Each timer interrupt has a separate vector type number.

⁵⁾ Default priorities for the interrupt sources are used only if the user does not program each source into a unique priority level.

Initialization and Processor Reset

Processor initialization or startup is accomplished by driving the \overline{RES} input pin low. \overline{RES} forces the SAB 80186 to terminate all execution and local bus activity. No instruction or bus activity will occur as long as \overline{RES} is active. After \overline{RES} becomes inactive and an internal processing interval elapses, the SAB 80186 begins execution with the instruction at physical location FFFF0(H). \overline{RES} also sets some registers to predefined values.

Initial Register State after RESET

Status Word	F002(H)
Instruction Pointer	0000(H)
Code Segment	FFFF(H)
Data Segment	0000(H)
Extra Segment	0000(H)
Stack Segment	0000(H)
Relocation Register	20FF(H)
UMCS	FFFB(H)

Clock Generator

The SAB 80186 provides an on-chip clock generator for both internal and external clock generation. The clock generator features a crystal oscillator, a divide-by-two counter, synchronous and asynchronous ready inputs and reset circuitry.

Oscillator

The oscillator circuit of the SAB 80186 is designed to be used with a parallel resonant fundamental mode crystal. This is used as the time base for the SAB 80186. The crystal frequency selected will be twice the CPU clock frequency. Use of an LC or RC circuit is not recommended with this oscillator. If an external oscillator is used, it can be connected directly to input pin X1 in lieu of a crystal. The output of the oscillator is not directly available outside the SAB 80186.

The following parameters may be used for choosing a crystal:

Temperature range	0 to 70 °C
ESR (equivalent series resistance)	30 Ω max.
C0 (shunt capacitance of crystal)	7.0 pF max.
C1 (load capacitance)	20 pF ± 2 pF
Drive level	1 mW max.

Ready Synchronization

The SAB 80186 provides both synchronous and asynchronous ready inputs. Asynchronous ready synchronization is accomplished by circuitry which samples ARDY in the middle of T2, T3 and again in the middle of each TW until ARDY is sampled high.

A second ready input (SRDY) is provided to interface with externally synchronized ready signals. This input is sampled at the end of T2, T3 and again at the end of each TW until it is sampled high.

Reset Logic

The SAB 80186 provides both a \overline{RES} input pin and a synchronized reset pin for use with other system components. The \overline{RES} input pin on the SAB 80186 is provided with hysteresis in order to facilitate power-on reset generation via an RC network.

Local Bus Controller

The SAB 80186 provides a local bus controller to generate the local bus control signals. In addition, it employs a HOLD/HLDA protocol for relinquishing the local bus to other bus masters. It also provides control lines that can be used to enable external buffers and to direct the flow of data on and off the local bus.

When the SAB 80186 relinquishes control of the local bus, it tristates \overline{DEN} , \overline{RD} , \overline{WR} , S_0 to S_2 , \overline{LOCK} , AD_0 to AD_{15} , A_{16} to A_{19} , \overline{BHE} , and DT/\overline{R} to allow another master to drive these lines directly.

Local bus controller and reset

Upon receipt of a reset pulse from the \overline{RES} input, the local bus controller will perform the following actions:

- Drive \overline{DEN} , \overline{RD} , and \overline{WR} high for one clock cycle, then float.
- Note:* \overline{RD} is also provided with an internal pullup device to prevent the processor from inadvertently entering queue status mode during reset.
- Drive S_0 to S_2 to the passive state (all high) and then float.
- Drive \overline{LOCK} high and then float.
- Tristate AD_0 to AD_{15} , A_{16} to A_{19} , \overline{BHE} , DT/\overline{R} .
- Drive ALE low (ALE is never tristated).
- Drive HLDA low.

Internal Peripheral Interface

All the SAB 80186 integrated peripherals are controlled via 16-bit registers contained within an internal 256 byte control block. This control block may be mapped into either memory or I/O space. Internal logic will recognize the address and respond to the bus cycle. During bus cycles to internal registers, the bus controller will signal the operation externally (i.e., the \overline{RD} , \overline{WR} , status, address, data, etc., lines will be driven as in a normal bus cycle), but D_{15} to D_0 , $SRDY$, and $ARDY$ will be ignored.

The control block base address is programmed via a 16-bit relocation register contained within the control block at offset FEH from the base address of the control block. It provides the upper 12 bits of the base address of the control block.

The integrated SAB 80186 peripherals operate semi-autonomously from the CPU. Access to them for the most part is via software read/write of the control and data locations in the control block. Most of these registers can be both read and written. A few dedicated lines, such as interrupts and DMA request provide real-time communication between the CPU and peripherals as in a more conventional system utilizing discrete peripheral blocks.

Internal Register Map

Chip Select Logic

The SAB 80186 contains logic which provides programmable chip select generation for both, memories and peripherals. In addition, it can be programmed to provide ready (or wait state) generation. It can also provide latched address bits A1 and A2. The chip select lines are active for all memory and I/O cycles in their programmed areas, whether they be generated by the CPU or by the integrated DMA unit.

Memory Chip Selects

The SAB 80186 provides 6 memory chip select outputs for 3 address areas: upper memory, lower memory, and midrange memory. One each is provided for upper memory and lower memory, while four are provided for midrange memory.

Upper Memory \overline{CS}

The SAB 80186 provides a chip select, called \overline{UCS} , for the top of memory. The top of memory is usually used as the system memory because after reset the SAB 80186 begins executing at memory location FFFF0H. After reset, the UMCS register is programmed for a 1 K area. It must be reprogrammed if a larger upper memory area is desired.

Lower Memory \overline{CS}

The SAB 80186 provides a chip select for low memory called \overline{LCS} . The bottom of memory contains the interrupt vector table, starting at location 00000H. After reset, the LMCS register value is undefined. However, the \overline{LCS} chip select line will not become active until the LMCS register is accessed.

Midrange Memory \overline{CS}

The SAB 80186 provides four \overline{MCS} lines which are active within a user-locatable memory block. This block can be located anywhere within the 1 Mbyte memory address space exclusive of the areas defined by \overline{UCS} and \overline{LCS} . Both the base address and size of this memory block are programmable.

Each of the four chip select lines is active for one of the four equal contiguous divisions of the midrange block. Thus, if the total block size is 32 K, each chip select is active for 8 K of memory with $\overline{MCS0}$ being active for the first range and $\overline{MCS3}$ being active for the last range. After reset, the contents of both of these registers is undefined.

However, none of the \overline{MCS} lines will be active until both the MMCS and MPSC registers are accessed.

Peripheral Chip Selects

The SAB 80186 can generate chip selects for up to seven peripheral devices. These chip selects are active for seven contiguous blocks of 128 bytes above a programmable base address. This base address may be located in either memory or I/O space.

Seven \overline{CS} lines called $\overline{PCS0-6}$ are generated by the SAB 80186. The base address is user-programmable; however it can only be a multiple of 1 Kbytes, i.e. the least significant 10 bits of the starting address are always 0.

$\overline{PCS5}$ and $\overline{PCS6}$ can also be programmed to provide latched address bits A1, A2. If so programmed, they cannot be used as peripheral selects.

The starting address of the peripheral chip select block is defined by the PACS register. This register is located at offset A4H in the internal control block. Bits 15 to 6 of this register correspond to bits 19 to 10 of the 20-bit Programmable Base Address (PBA) of the peripheral chip-select block.

PCS Address Ranges

PCS Line	Active between Locations
PCS0	PBA – PBA+127
PCS1	PBA+128 – PBA+255
PCS2	PBA+256 – PBA+383
PCS3	PBA+384 – PBA+511
PCS4	PBA+512 – PBA+639
PCS5	PBA+640 – PBA+767
PCS6	PBA+768 – PBA+895

Ready Generation Logic

The SAB 80186 can generate a ready signal internally for each of the memory or peripheral CS lines. The number of wait states to be inserted for each peripheral or memory is programmable to provide 0 to 3 wait states for all accesses to the area for which the chip select is active. In addition, the SAB 80186 may be programmed to either ignore external ready for each chip select range individually or to factor external ready with the integrated ready generator.

Ready control consists of 3 bits for each CS line or group of lines generated by the SAB 80186.

Chip Select/Ready Logic and Reset

Upon reset, the chip select/ready logic will perform the following actions:

- All chip select outputs will be driven high.
- Upon leaving reset, the UCS line will be programmed to provide chip selects to a 1 K block with the accompanying ready control bits set at 011 to allow the maximum number of internal wait states in conjunction with external ready consideration (i.e. UMCS resets to FFFBH).
- No other chip select or ready control registers have any predefined values after reset. They will not become active until the CPU accesses their control registers. Both the PACS and MPCS registers must be accessed before the PCS lines will become active.

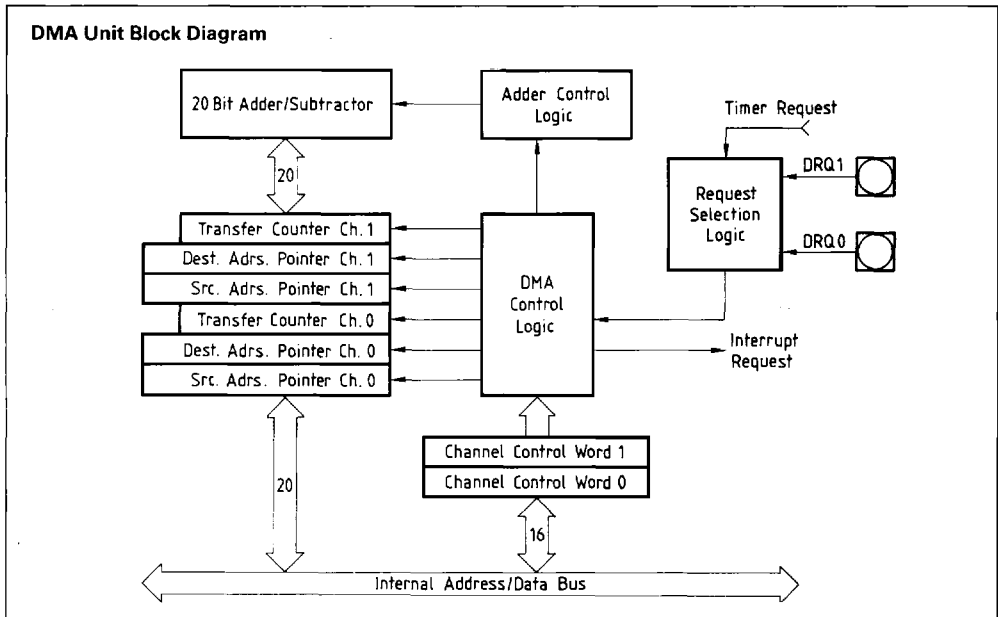

DMA Channels

The SAB 80186 DMA controller provides two independent high-speed DMA channels. Data transfers can occur between memory and I/O spaces (e.g., Memory-to-I/O) or within the same space (e.g., Memory-to-Memory or I/O-to-I/O). Data can be transferred either in bytes (8 bits) or in words (16 bits) to or from even or odd addresses. Each DMA channel maintains both a 20-bit source and destination pointer which can be optionally incremented or decremented after each data transfer (by one or two depending on byte or word transfers). Each data transfer consumes 2 bus cycles (a minimum of 8 clocks), one cycle to fetch data and the other to store data. This provides a maximum data transfer rate of one Mword/s or 2 Mbytes/s.

DMA Channel Control Word Register

Each DMA channel control word determines the mode of operation for the particular SAB 80186 DMA channel.

The DMA channel control registers may be changed while the channel is operating. However, any changes made during operation will affect the current DMA transfer.

DMA Control Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Destination Pointer (upper 4 bits)	C6H	D6H
Destination Pointer (lower 4 bits)	C4H	D4H
Source Pointer (upper 4 bits)	C2H	D2H
Source Pointer (lower 4 bits)	C0H	D0H

DMA Control Word Bit Description

\bar{B} /W Byte/word (0/1) transfers.
 ST/STOP Start/stop (1/0) channel.
 CHG/NOCHG Change/do not change (1/0) ST/STOP bit. If this bit is set when writing to the control word, the ST/STOP bit will be programmed by the write to the control word. If this bit is cleared when writing the control word, the ST/STOP bit will not be altered. This bit is not stored; it will always be a 0 on read.
 INT Enable interrupts to CPU on transfer count termination.
 TC If set, DMA will terminate when the contents of the transfer count register reach zero. The ST/STOP bit will also be reset at this point if TC is set. If this bit is cleared, the DMA unit will decrement the transfer count register for each DMA cycle, but the DMA transfer will not stop when the contents of the TC register reach zero.
 SYN (2 bits) 00 No synchronization.
 Note: The ST bit will be cleared automatically when the contents of the TC register reach zero regardless of the state of the TC bit.
 01 Source synchronization.
 10 Destination synchronization.
 11 Unused.

TDRQ 0: Disable DMA requests from timer 2.
 1: Enable DMA requests from timer 2.
 Bit 3 Bit 3 is not used.
 Source: INC Increment source pointer by 1 or 2 (depends on \bar{B} /W) after each transfer.
 M/ \bar{I} O Source pointer is in M/IO space (1/0).
 DEC Decrement source pointer by 1 or 2 (depends on \bar{B} /W) after each transfer.
 Destin.: INC Increment destination pointer by 1 or 2 (\bar{B} /W) after each transfer.
 M/ \bar{I} O Destination pointer is in M/IO space (1/0).
 DEC Decrement destination pointer by 1 or 2 (depending on \bar{B} /W) after each transfer.
 P Channel priority – relative to other channel.
 0 low priority.
 1 high priority.
 Channels will alternate cycles if both set at same priority level.

DMA Destination and Source Pointer Register

Each DMA channel maintains a 20-bit source and a 20-bit destination pointer. Each of these pointers takes up two full 16-bit registers in the peripheral control block. The lower four bits of the upper register contain the upper four bits of the 20-bit physical address.

DMA Transfer Count Register

Each DMA channel maintains a 16-bit transfer count register (TC). This register is decremented after every DMA cycle, regardless of the state of the TC bit in the DMA control register.

DMA Requests

Data transfers may be either source or destination synchronized, that is either the source of the data or the destination of the data may request the data transfer. In addition, DMA transfers may be un-

synchronized; that is, the transfer will take place continually until the correct number of transfers has occurred.

DMA Priority

The DMA channels may be programmed such that one channel is always given priority over the other, or they may be programmed such as to alternate cycles when both have DMA requests pending. DMA cycles always have priority over internal CPU cycles except between locked memory accesses or word accesses to odd memory locations; however, an external bus hold takes priority over an internal DMA cycle.

DMA Channels and Reset

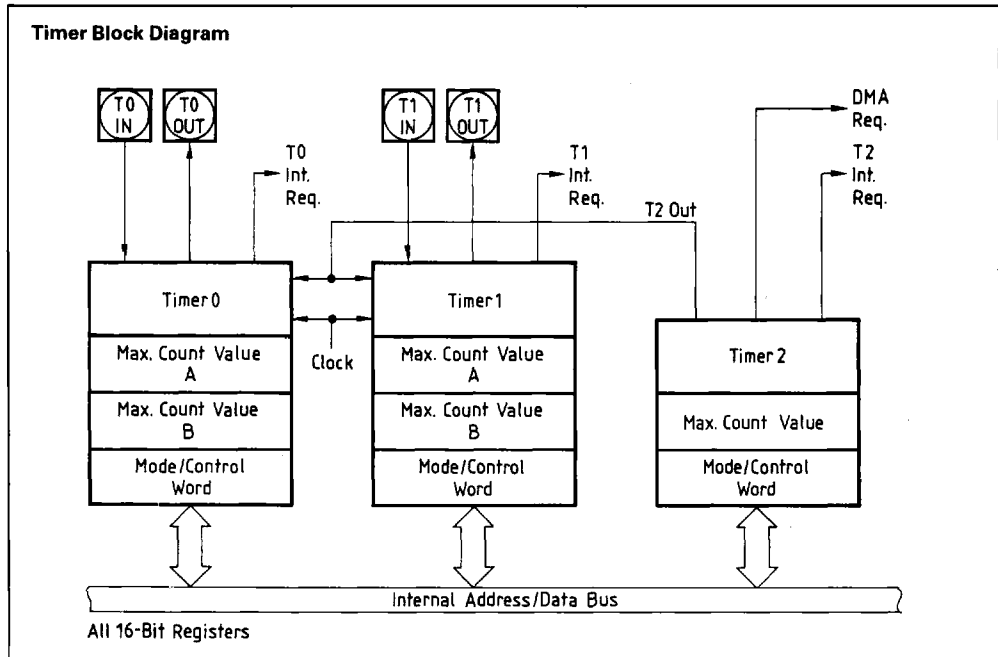

Upon reset, the DMA channels will perform the following actions:

- The start/stop bit for each channel will be reset to STOP.
- Any transfer in progress is aborted.

Timers

The SAB 80186 provides three internal 16-bit programmable timers. Two of these are highly flexible and are connected to four external pins (2 per timer). They can be used to count external events, time external events, generate nonrepetitive waveforms,

etc. The third timer is not connected to any external pins, and is useful for real-time coding and time delay applications. In addition, this third timer can be used as a prescaler to the other two, or as a DMA request source.

Timer Mode/Control Register

Timer Control Block Format

Register Name	Register Offset		
	TMR 0	TMR 1	TMR 2
Mode/Control Word	56H	5EH	66H
Max. Count B	54H	5CH	not present
Max. Count A	52H	5AH	62H
Count Register	50H	58H	60H

Timer Operation

The timers are controlled by eleven 16-bit registers in the internal peripheral control block. The count register contains the current value of the timer. It can be read or written at any time independent of whether the timer is running or not. The value of this register will be incremented for each timer event. Each of the timers is equipped with a max. count register, which defines the maximum count the timer will reach. After reaching the max. count register value, the timer count value will be reset to zero during that same clock.

Each timer gets serviced every fourth CPU clock cycle, and thus can operate at speeds up to one-quarter the internal clock frequency (one-eighth the crystal rate). External clocking of the timers may be done at up to a rate of one-quarter of the internal CPU clock rate (2 MHz for an 8 MHz CPU clock).

The timers have several programmable options.

- All three timers can be set to halt or continue on a terminal count.
- Timers 0 and 1 can select between internal and external clocks, alternate between max. count registers and be set to retrigger on external events.
- The timers may be programmed to cause an interrupt on terminal count.

Count Registers

Each of the three timers has a 16-bit count register. The current contents of this register may be read or written by the processor at any time. If the register is written into while the timer is counting, the new value will take effect in the current count cycle.

Max. Count Registers

Timers 0 and 1 have two max.count registers, while timer 2 has a single max.count register. These contain the number of events the timer will count. In timers 0 and 1, the max.count register used can alternate between the two max.count values whenever the current maximum count is reached.

Timer Mode/Control Register

The mode/control register allows the user to program the specific mode of operation or check the current programmed status for any of the three integrated timers.

ALT:

The ALT bit determines which of two max. count registers is used for count comparison. If ALT = 0, register A for that timer is always used, while if ALT = 1, the comparison will alternate between register A and register B when each maximum count is reached. This alternation allows the user to change one max.count register while the other is being used, and thus provides a method of generating nonrepetitive waveforms. Square waves and pulse outputs of any duty cycle are a subset of available signals obtained by not changing the final count registers. The ALT bit also determines the function of the timer output pin. If ALT is zero, the output pin will go low for one clock, the clock after the maximum count is reached. If ALT is one, the output pin will reflect the current max.count register being used (0/1 for B/A).

CONT:

Setting the CONT bit causes the associated timer to run continuously, while resetting it causes the timer to halt upon maximum count. If CONT = 0 and ALT = 1, the timer will count to the max. count register A value, be reset, count to the register B value, be reset, and halt.

EXT:

The external bit selects between internal and external clocking for the timer. The external signal may be asynchronous with respect to the SAB 80186 clock. If EXT is set, the timer will count low-to-high transitions on the input pin. If cleared, it will count an internal clock while using the input pin for control. In this mode, the function of the external pin is defined by the RTG bit. The maximum input-to-output transition latency time may be as much as 6 clocks. However, clock inputs may be pipelined as closely together as every 4 clocks without losing clock pulses.

P:

The prescaler bit is ignored unless internal clocking has been selected (EXT = 0). If the P bit is a zero, the timer will count at one-fourth the internal CPU clock rate. If the P bit is a one, the output of timer 2 will be used as a clock for the timer. Note that the user must initialize and start timer 2 to obtain the prescaled clock.

RTG:

Retrigger bit is only active for internal clocking (EXT = 0). In this case it determines the control function provided by the input pin.

If RTG = 0, the input level gates the internal clock on and off. If the input pin is high, the timer will count; if the input pin is low, the timer will hold its value. As indicated previously, the input signal may be asynchronous with respect to the SAB 80186 clock.

When RTG = 1, the input pin detects low-to-high transitions. The first transition starts the timer running, clearing the timer value to zero on the first clock, and then incrementing thereafter. Further transitions on the input pin will again reset the timer to zero, from which it will start counting up again. If CONT = 0, when the timer has reached maximum count, the EN bit will be cleared, inhibiting further timer activity.

EN:

The enable bit provides programmer control over the timer's RUN/HALT status. When set, the timer is enabled to increment subject to the input pin constraints in the internal clock mode (discussed previously). When cleared, the timer will be inhibited from counting. All input pin transitions during which the time EN is zero will be ignored. If CONT is zero, the EN bit is automatically cleared upon maximum count.

INH:

The inhibit bit allows for selective updating of the enable (EN) bit. If INH is a one during the write to the mode/control word, then the state of the EN bit will be modified by the write. If INH is a zero during the write, the EN bit will be unaffected by the operation. This bit is not stored; it will always be a 0 on a read.

INT:

When set, the INT bit enables interrupts from the timer, which will be generated on every terminal count. If the timer is configured in dual max.count register mode, an interrupt will be generated each time the value in max.count register A is reached, and each time the value in max.count register B is reached. If this enable bit is cleared after the interrupt request has been generated, but before a pending interrupt is serviced, the interrupt request will still be in force. (The request is latched in the interrupt controller.)

MC:

The maximum count bit is set whenever the timer reaches its final maximum count value. If the timer is configured in dual max.count register mode, this bit will be set each time the value in max.count register A is reached, and each time the value in max.count register B is reached. This bit is set regardless of the timer's interrupt enable bit. The MC bit gives the user the ability to monitor timer status through software instead of through interrupts.

Programmer intervention is required to clear this bit.

RIU:

The register in use bit indicates which max.count register is currently being used for comparison to the timer count value. A zero indicates register A. The RIU bit cannot be written, i.e. its value is not affected when the control register is written. It is always cleared when the ALT bit is zero.

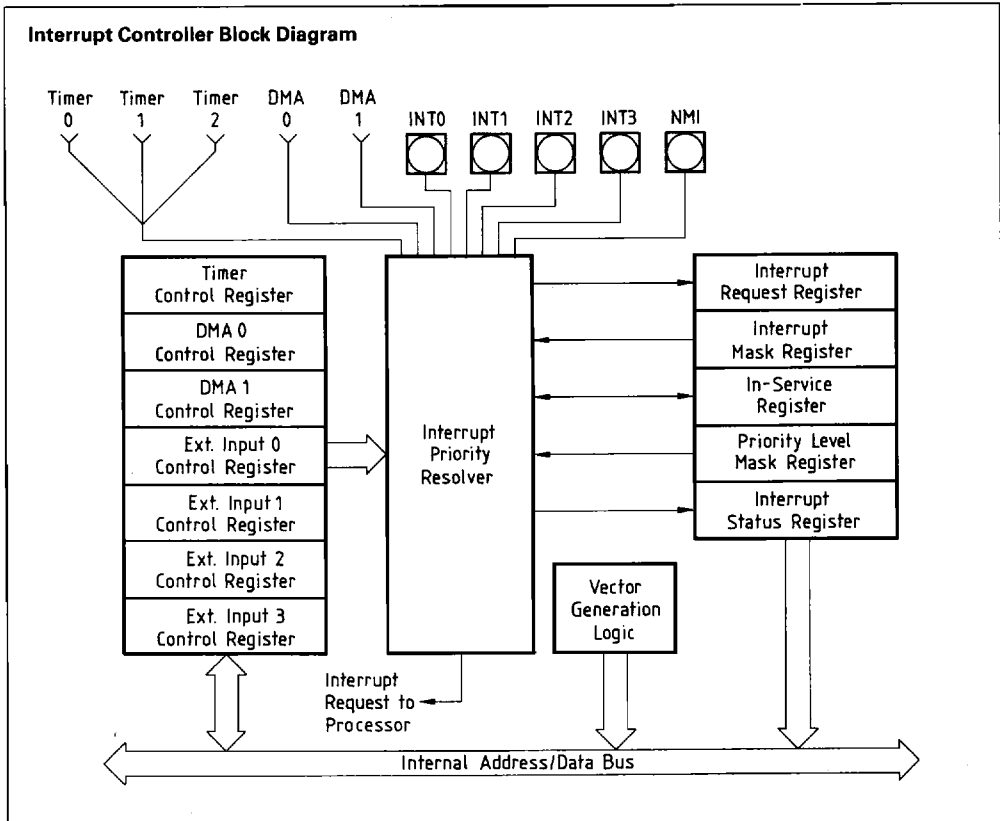

Not all mode bits are provided for timer 2. Certain bits are hardwired as indicated below:

ALT = 0, EXT = 0, P = 0, RTG = 0, RIU = 0

Timers and Reset

Upon reset, the timers will perform the following actions:

- All EN (enable) bits are reset preventing timer counting.
- All SEL (select) bits are reset to zero. This selects max. count register A, resulting in the timer-out pins going high upon reset.

Interrupt Controller

The SAB 80186 can receive interrupts from a number of sources, both internal and external. The internal interrupt controller serves to merge these requests on a priority basis, for individual service by the CPU. Internal interrupt sources (timers and DMA channels) can be disabled by their own control registers or by mask bits within the interrupt controller. The SAB 80186 interrupt controller has its own control registers that set the mode of operation for the controller.

The interrupt controller will resolve priority among requests that are pending simultaneously. Nesting is provided so interrupt service routines for lower priority interrupts may themselves be interrupted by higher priority interrupts.

The interrupt controller has a special iRMX 86 compatibility mode that allows the use of the SAB 80186 within the iRMX 86 operating system interrupt structure.

Master Mode Operation

Interrupt Controller External Interface

For external interrupt sources, five dedicated pins are provided. One of these pins is dedicated to NMI, non-maskable interrupt. This is typically used for power-fail interrupts, etc. The other four pins may function either as four interrupt input lines with internally generated interrupt vectors, as an interrupt line and an interrupt acknowledge line (called the "cascade mode") along with two other input lines with internally generated interrupt vectors, or as two interrupt input lines and two dedicated interrupt acknowledge output lines. When the interrupt lines are configured in cascade mode, the SAB 80186 interrupt controller will not generate internal interrupt vectors.

Interrupt Controller Modes of Operation

The basic modes of operation of the interrupt controller in master mode are similar to the SAB 8259A. The interrupt controller responds identical to internal interrupts in all three modes: the difference is only in the interpretation of function of the four external interrupt pins.

Fully nested mode

When in fully nested mode, four pins are used as direct interrupt requests. The vectors for these four inputs are generated internally. An in-service bit (IS) is provided for every interrupt source. If a lower priority device requests an interrupt while the in-service bit is set, no interrupt will be generated by the interrupt controller. In addition, if another interrupt request occurs from the same interrupt source while the in-service bit is set, no interrupt will be generated by the interrupt controller. When a service routine is completed, the proper IS bit must be reset by writing the proper pattern to the EOI register.

Cascade mode

The SAB 80186 has four interrupt pins and two of them have dual functions. In fully nested mode, the four pins are used as direct interrupt inputs and the corresponding vectors are generated internally. In cascade mode, the four pins are configured into interrupt input-dedicated acknowledge signal pairs. INT0 is an interrupt input interfaced to an SAB 8259A, while INT2/ $\overline{\text{INTA}}_0$ serves as the dedicated interrupt acknowledge signal to the peripheral. The same is true for INT1 and INT3/ $\overline{\text{INTA}}_1$. Each pair can selectively be placed in the cascade or non-cascade mode by programming the proper value INT0 and INT1 control registers.

The primary cascade mode allows the capability to serve up to 128 external interrupt sources through the use of external master and slave SAB 8259As.

Special fully nested mode

This mode is entered by setting the SFNM bit in INTO or INT1 control register. It enables complete nestability with external SAB 8259A masters. In special fully nested mode, the SAB 80186 interrupt controller will allow interrupts from an external pin regardless of the state of the in-service bit for an interrupt source in order to allow multiple interrupts from a single pin.

Polling operation

The controller may be used in a polled mode if interrupts are undesirable. When polling, the processor disables interrupts and then polls the interrupt controller whenever it is convenient. Polling the interrupt controller is accomplished by reading the poll word. Bit 15 in the poll word indicates to the processor that an interrupt of high enough priority is requesting service.

Master Mode Features

Programmable priority

The user can program the interrupt sources into any of eight different priority levels. The programming is done by placing a 3-bit priority level (0 to 7) in the control register of each interrupt source.

End-of-interrupt command

The end-of-interrupt (EOI) command is used by the programmer to reset the in-service (IS) bit when an interrupt service routine is completed. The EOI command is issued by writing the proper pattern to the EOI register. There are two types of EOI commands, specific and nonspecific. The non-specific command does not specify which IS bit is reset.

Trigger mode

The four external interrupt pins can be programmed in either edge or level-trigger mode. The control register for each external source has a level-trigger mode (LTM) bit. All interrupt inputs are active high. In the edge-sense mode or the level-trigger mode, the interrupt request must remain active (high) until the interrupt request is acknowledged by the SAB 80186 CPU. In the edge-sense mode, if the level remains high after the interrupt is acknowledged, the input is disabled and no further requests will be generated. The input level must go low for at least one clock cycle to reenable the input.

Interrupt vectoring

The SAB 80186 interrupt controller will generate interrupt vectors for the integrated DMA channels and the integrated timers. In addition, the interrupt controller will generate interrupt vectors for the external interrupt lines if they are not configured in cascade or special fully nested mode.

Interrupt Controller Registers

In-service register

This register contains the in-service bit for each of the interrupt sources. The in-service bit is set to indicate that a source's service routine is in progress. When an in-service bit is set, the interrupt controller will not generate interrupts to the CPU when it receives interrupt requests from devices with a lower programmed priority level. The TMR bit is the in-service bit for all three timers; the D0 and D1 bits are the in-service bits for the two DMA channels; the I0 – I3 bits are the in-service bits for the external interrupt pins.

Interrupt request register

The internal interrupt sources have interrupt request bits inside the interrupt controller. A read from this register yields the status of these bits. The TMR bit is the logical OR of all timer interrupt requests. D0 and D1 are the interrupt request bits for the DMA channels.

Mask register

This is a 16-bit register that contains a mask bit for each interrupt source. A one in a bit position corresponding to a particular source serves to mask the source from generating interrupts. These mask bits are exactly the same bits which are used in the individual control registers.

Priority mask register

This register is used to mask all interrupts below particular interrupt priority levels. The code in the lower three bits of this register inhibits interrupts of priority lower (a higher priority number) than the code specified.

Interrupt status register

This register contains general interrupt controller status information. The bits in the status register have the following functions:

- DHLT:** DMA halt transfer; setting this bit halts all DMA transfers. It is automatically set whenever a non-maskable interrupt occurs, and it is reset when an IRET instruction is executed.
- IRTx:** These three bits represent the individual timer interrupt request bits. These bits are used to differentiate the timer interrupts, since the timer IR bit in the interrupt request register is the "OR" function of all timer interrupt requests.

Timer, DMA 0, 1 control registers

These registers are the control words for all the internal interrupt sources. The three bit positions PR0, PR1, and PR2 represent the programmable priority level of the interrupt source. The MSK bit inhibits interrupt requests from the interrupt source. The MSK bits in the individual control registers are exactly the same bits as are in the mask register; modifying them in the individual control registers will also modify them in the mask register, and vice versa.

INT0 to INT3 control registers

These registers are the control words for the four external input pins. In cascade mode or special fully nested mode, the control words for INT2 and INT3 are not used.

- PR0-2:** Priority programming information.
Highest priority = 000, lowest priority = 111

- LTM:** Level-trigger mode bit. 1 = level-triggered; 0 = edge-triggered. Interrupt input levels are active high. In level-triggered mode, an interrupt is generated whenever the external line is high. In edge-triggered mode, an interrupt will be generated only when this level is preceded by an inactive-to-active transition on the line. In both cases, the level must remain active until the interrupt is acknowledged.

- MSK:** Mask bit, 1 = mask; 0 = nonmask.

- C:** Cascade mode bit, 1 = cascade; 0 = direct

- SFNM:** Special fully nested mode bit, 1 = SFNM

EOI register

The end-of-interrupt register is a command register which can only be written into. It initiates an EOI command when written to by the SAB 80186 CPU.

- S_x:** Encoded information that specifies an interrupt source vector type

- NSPEC/:** A bit that determines the type of EOI command. Nonspecific = 1, specific = 0.

Poll and poll status registers

These registers contain polling information. They can only be read. Reading the poll register constitutes a software poll. This will set the IS bit of the highest priority pending interrupt.

- S_x:** Encoded information that indicates the vector type of the highest priority interrupting source. Valid only when INTREQ = 1.

- INTREQ:** This bit determines if an interrupt request is present. Interrupt request = 1; no interrupt request = 0.

iRMX 86 Compatibility Mode

This mode allows iRMX 86-SAB 80186 compatibility. The interrupt model of iRMX 86 requires one master and multiple slave SAB 8259As in cascaded mode. When iRMX mode is used, the internal SAB 80186 interrupt controller will be used as a slave controller to an external master interrupt controller. Upon reset, the SAB 80186 interrupt controller will be in the non-iRMX 86 mode of operation. To set the controller in the iRMX 86 mode, bit 14 of the relocation register should be set.

The iRMX 86 operating system requires peripherals to be assigned fixed priority levels. This is incompatible with the normal operation of the SAB 80186 interrupt controller. Therefore, the initialization software must program the proper priority levels for each source.

Required iRMX Internal Source Priority Levels

Priority Level	Interrupt Source
0	Timer 0
1	(reserved)
2	DMA 0
3	DMA 1
4	Timer 1
5	Timer 2

iRMX 86 Mode External Interface

In the iRMX 86 configuration of the SAB 80186 the INT0 input is used as the SAB 80186 CPU interrupt input. INT3 functions as an output to send the SAB 80186 slave-interrupt-request to one of the 8 master PIC inputs. Correct master-slave interface requires decoding of the slave addresses (CAS0-2). Slave SAB 8259As do this internally. Because of pin limitations, the SAB 80186 slave address will have to be decoded externally. INT1 is used as a slave-select input.

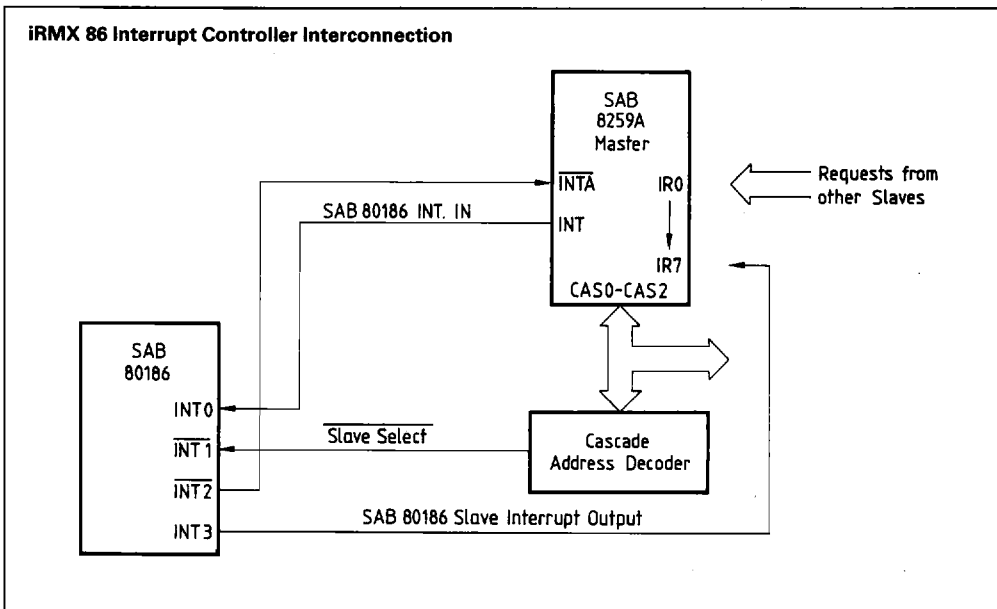

INT2 is used as an acknowledge output, suitable to drive the INTA input of an SAB 8259A.

Vector Generation in the iRMX 86 Mode

Vector generation in iRMX mode is exactly like that of an SAB 8259A slave. The interrupt controller generates an 8-bit vector which the CPU multiplies by four and uses as an address into a vector table. The significant five bits of the vector are user-programmable while the lower three bits are generated by the priority logic.

Specific End-of-Interrupt

In iRMX mode the specific EOI command operates to reset an in-service bit of a specific priority. The user supplies a 3-bit priority-level value that points to an in-service bit to be reset.

Interrupt Controller Registers in the iRMX 86 Mode**End-of-interrupt register**

The end-of-interrupt register is a command register which can only be written to. It initiates an EOI command when written to by the SAB 80186 CPU.

Lx: Encoded value indicating the priority of the IS bit to be reset.

In-service register

This register contains the in-service bit for each of the internal interrupt sources. Bit positions 2 and 3 correspond to the DMA channels; positions 0, 4, and 5 correspond to the integral timers.

Interrupt request register

This register indicates which internal peripherals have interrupt requests pending. The interrupt request bits are set when a request arrives from an internal source, and are reset when the processor acknowledges the request.

Mask register

This register contains a mask bit for each interrupt source. If the bit in this register corresponding to a particular interrupt source is set, any interrupts from that source will be masked.

Control registers

These registers are the control words for all the internal interrupt sources.

PRx: 3-bit encoded field indicating a priority level for the source; note that each source must be programmed at specified levels.

MSK: Mask bit for the priority level indicated by PRx bits.

Interrupt vector register

This register provides the upper five bits of the interrupt vector address. The interrupt controller itself provides the lower three bits of the interrupt vector as determined by the priority level of the interrupt request.

The format of the bits in this register is:

tx: 5-bit field indicating the upper five bits of the vector address.

Priority-level mask register

This register indicates the lowest priority-level interrupt which will be serviced.

The encoding of the bits in this register is:

mx: 3-bit encoded field indicating priority-level value. All levels of lower priority will be masked.

Interrupt status register

This register is defined exactly as in non-iRMX mode.

Interrupt Controller and Reset

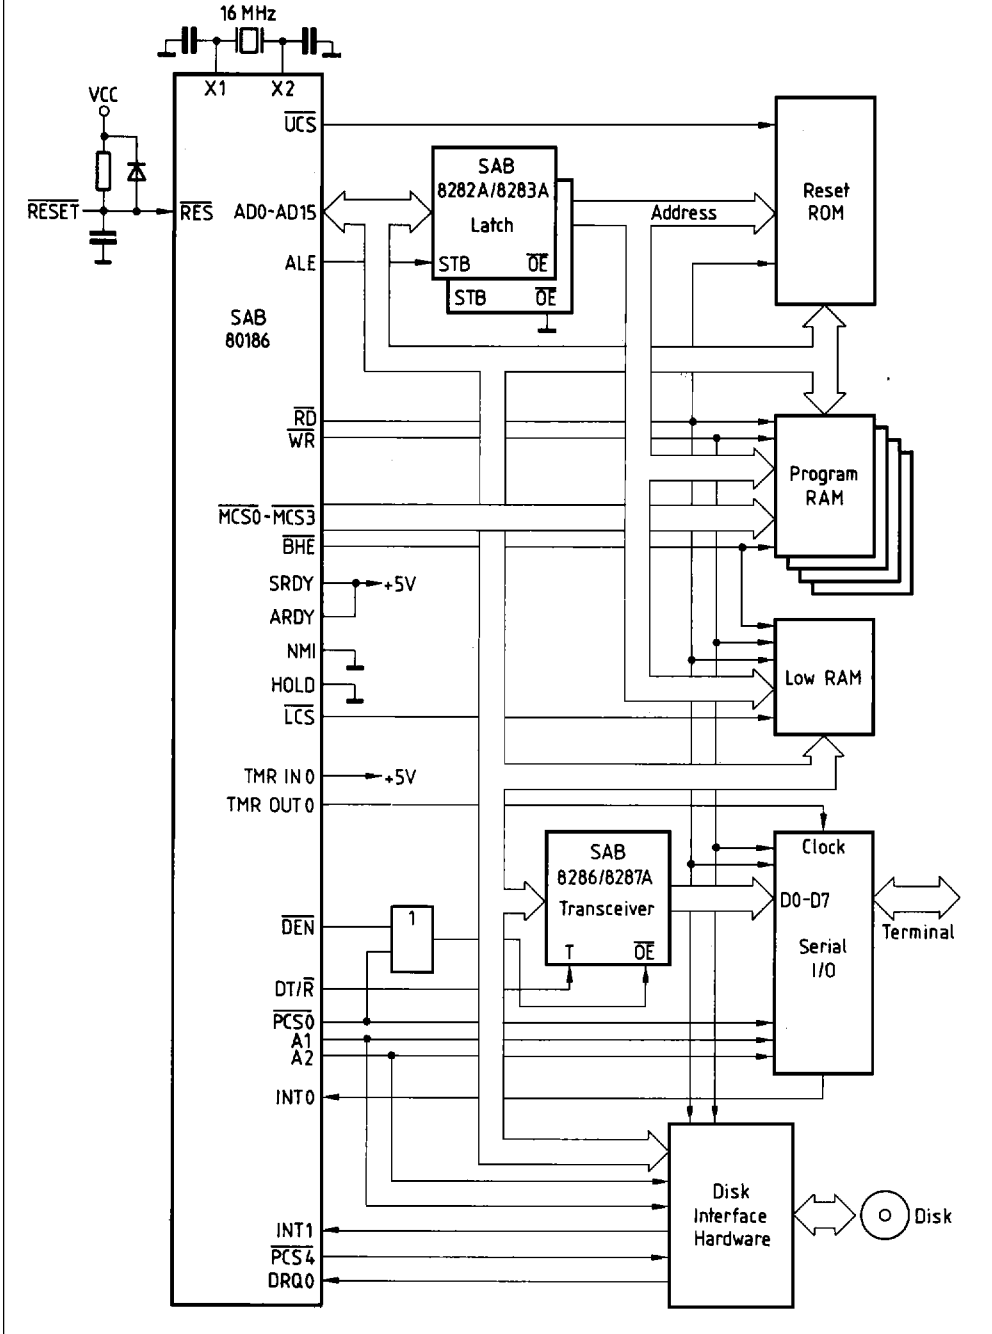

Upon reset, the interrupt controller will perform the following actions:

- All SFNM bits reset to 0, implying fully nested mode.
- All PR bits in the various control registers set to 1. This places all sources at lowest priority (level 111).
- All LTM bits reset to 0, resulting in edge-sense mode.
- All interrupt service bits reset to 0.
- All interrupt request bits reset to 0.
- All MSK (interrupt mask) bits set to 1 (mask).
- All C (cascade) bits reset to 0 (non-cascade).
- All PRM (Priority mask) bits set to 1, implying no levels masked.
- Initialized to non-iRMX 86 mode.

Typical SAB 80186 Multimaster Bus Interface

Typical SAB 80186 System Configuration

Instruction Timings

The following instruction timings represent the minimum execution time in clock cycles for each instruction. The timings given are based on the following assumptions:

- The op code, along with any data or displacement required for execution of a particular instruction, has been prefetched and resides in the queue at the time it is needed.
- No wait states or bus HOLDs occur.

Notes:

The effective address (EA) of the memory operand is computed according to the mod and r/m fields:

- if mod = 11 then r/m is treated as a REG field
- if mod = 00 then DISP = 0*, disp-low and disp-high are absent
- if mod = 01 then DISP = disp-low sign-extended to 16-bits, disp-high is absent
- if mod = 10 then DISP = disp-high: disp-low
- if r/m = 000 then EA = (BX) + (SI) + DISP
- if r/m = 001 then EA = (BX) + (DI) + DISP
- if r/m = 010 then EA = (BP) + (SI) + DISP
- if r/m = 011 then EA = (BP) + (DI) + DISP
- if r/m = 100 then EA = (SI) + DISP
- if r/m = 101 then EA = (DI) + DISP
- if r/m = 110 then EA = (BP) + DISP*
- if r/m = 111 then EA = (BX) + DISP

DISP follows 2nd byte of instruction (before data if required)

* except if mod = 00 and r/m = 110 then EA = disp-high: disp-low

Note: EA calculation time is 4 clock cycles for all modes, and is included in the execution times given whenever appropriate.

Segment override prefix

0 0 1 reg 1 1 0

reg is assigned according to the following:

reg	Segment register
00	ES
01	CS
10	SS
11	DS

- All word data is located on even-address boundaries.

All jumps and calls include the time required to fetch the op code of the next instruction at the destination address.

All instructions which involve memory reference can require one (and in some cases, two) additional clocks above the minimum timings shown. This is due to the asynchronous nature of the handshake between the BIU and the execution unit.

REG is assigned according to the following table:

16-bit (w = 1)	8-bit (w = 0)
000 AX	000 AL
001 CX	001 CL
010 DX	010 DL
011 BX	011 BL
100 SP	100 AH
101 BP	101 CH
110 SI	110 DH
111 DI	111 BH

The physical addresses of all operands addressed by the BP register are computed using the SS segment register. The physical addresses of the destination operands of the string primitive operations (those addressed by the DI register) are computed using the ES segment, which may not be overridden.

Instruction Set Summary

Function	Format	Clock Cycles	Comments
Data Transfer MOV = Move:

Absolute Maximum Ratings

Ambient temperature under bias	0 to 70°C
Storage temperature	-65 to +150°C
Voltage on any pin with respect to ground	-0.5 to +7V
Power dissipation	3 W

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

DC Characteristics

$T_A = 0$ to 70°C ; $V_{CC} = 5\text{ V} \pm 10\%$

Parameter	Symbol	Limit values		Unit	Test conditions
		min.	max.		
Input low voltage	V_{IL}	-0.5	+0.8	V	-
Input high voltage (all except X1 and RES)	V_{IH}	2.0	$V_{CC} + 0.5$	V	-
Input high voltage (RES)	V_{IH1}	3.0	$V_{CC} + 0.5$	V	-
Output low voltage	V_{OL}	-	0.45	V	$I_a = 2.5\text{ mA}$ for S0-S2 $I_a = 2.0\text{ mA}$ for all other outputs
Output high voltage	V_{OH}	2.4	-	V	$I_{OA} = -400\ \mu\text{A}$
Power supply current	I_{CC}	-	550	mA	$T_A = 0^\circ\text{C}$
		-	450	mA	$T_A = 70^\circ\text{C}$
Input leakage current	I_{LI}	-	± 10	μA	$0\text{ V} < V_{IN} < V_{CC}$
Output leakage current	I_{LO}	-	± 10	μA	$0.45\text{ V} < V_{OUT} < V_{CC}$
Clock output low	V_{CLO}	-	0.6	V	$I_A = 4.0\text{ mA}$
Clock output high	V_{CHO}	4.0	-	V	$I_{OA} = -200\ \mu\text{A}$
Clock input low voltage	V_{CLI}	-0.5	0.6	V	-
Clock input high voltage	V_{CHI}	3.9	$V_{CC} + 1.0$	V	-
Input capacitance	C_{IN}	-	10	pF	-
I/O capacitance	C_{IO}	-	20	pF	-

AC Characteristics

$T_A = 0$ to 70°C , $V_{CC} = 5\text{V} \pm 10\%$

Timing Requirements: all timings measured at 1.5V unless otherwise specified

CLKOUT fall time	t_{CL2CL1}	–	15	–	12	ns	3.5 to 1.0 V

Major Cycle Timing (cont'd)

Notes

- 1) Following a write cycle, the local bus is tristated by the SAB 80186 only when the SAB 80186 enters a "hold acknowledge" state.
- 2) INTA occurs one clock later in iRMX mode.
- 3) Status inactive just prior to T4.

CLKOUT Timing Relationships

Ready Timing

HOLD-HLDA Timing
