

Advance Information
**High Speed Single-Ended
 PWM Controller**

The MC34023 series are high speed, fixed frequency, single-ended pulse width modulator controllers optimized for high frequency operation. They are specifically designed for Off-Line and DC-to-DC converter applications offering the designer a cost-effective solution with minimal external components. These integrated circuits feature an oscillator, a temperature compensated reference, a wide bandwidth error amplifier, a high speed current sensing comparator, and a high current totem pole output ideally suited for driving power MOSFET.

Also included are protective features consisting of input and reference undervoltage lockouts each with hysteresis, cycle-by-cycle current limiting, and a latch for single pulse metering.

The flexibility of this series allows it to be easily configured for either current mode or voltage mode control.

- 50 ns Propagation Delay to Output
- High Current Totem Pole Output
- Wide Bandwidth Error Amplifier
- Fully-Latched Logic with Double Pulse Suppression
- Latching PWM for Cycle-By-Cycle Current Limiting
- Soft-Start Control with Latched Overcurrent Reset
- Input Undervoltage Lockout with Hysteresis
- Low Start-Up Current (400 μ A Typ)
- Internally Trimmed Reference with Undervoltage Lockout
- 90% Maximum Duty Cycle (Externally Adjustable)
- Precision Trimmed Oscillator
- Voltage or Current Mode Operation to 1.0 MHz
- Designed Replacement for the UC3823

OPERATING DESCRIPTION

3

The MC33023 and MC34023 series are high speed, fixed frequency, single-ended pulse width modulator controllers optimized for high frequency operation. They are specifically designed for Off-Line and DC-to-DC converter applications offering the designer a cost effective solution with minimal external components. A representative block diagram is shown in Figure 18.

Oscillator

The oscillator frequency is programmed by the values selected for the timing components R_T and C_T . The R_T pin is set to a temperature compensated 3.0 V. By selecting the value of R_T , the charge current is set through a current mirror for the timing component (C_T). This charge current runs continuously through C_T . The discharge current is ratioed to be 10 times the charge current, which yields the maximum duty cycle of 90%. C_T is charged to 2.8 V and discharged to 1.0 V. During the discharge of C_T , the oscillator generates an internal blanking pulse that resets the PWM Latch, inhibits the outputs, and toggles the steering flip-flop. The threshold voltages on the oscillator comparator is trimmed to guarantee an oscillator accuracy of 5.0% at 25°C.

Additional dead time can be added by externally increasing the charge current to C_T . This changes the charge to discharge ratio of C_T which is set internally to $I_{charge}/10 I_{charge}$. The new charge to discharge ratio will be:

$$\% \text{ Deadtime} = \frac{I_{\text{additional}} + I_{\text{charge}}}{10 (I_{\text{charge}})}$$

A bidirectional clock pin is provided for synchronization or for master/slave operation. When synchronizing the MC34023 to an external clock source, the oscillator should be set about 10% less than the external clock frequency. If master/slave operation of more than one MC34023 is desired, the master IC should have the desired R_T , C_T values. The clock pin of the master is connected to the clock pin on the slave(s). The R_T pin on the slave(s) should be connected to V_{ref} and the C_T pin should be connected to ground. If the master IC is not close to the slave IC(s), the clock pin should be buffered. Refer to Figures 27, 28, and 29 for some application hints.

Error Amplifier

A fully compensated Error Amplifier is provided. It features a typical DC voltage gain of 95 dB and a unity gain bandwidth of 5.5 MHz with 75 degrees of phase margin (Figure 3). Typical application circuits will have the noninverting input tied to the reference. The inverting input will typically be connected to a feedback voltage generated from the output of the switching power supply. The Error Amplifier Output is provided for external loop compensation.

Soft-Start Latch

Soft-Start is accomplished in conjunction with an external capacitor. The Soft-Start capacitor is charged by an internal 10 μ A current source. This capacitor clamps the output of

the error amplifier to less than its normal output voltage, thus limiting the duty cycle. The time it takes for a capacitor to reach full charge is given by:

$$t \approx (4.5 \cdot 10^5) C_{\text{Soft-Start}}$$

A Soft-Start latch is incorporated to prevent erratic operation of this circuitry. Two conditions can cause the Soft-Start circuit to latch so that the Soft-Start capacitor stays discharged. The first condition is activation of an undervoltage lockout of either V_{CC} or V_{ref} . The second condition is when current sense input exceeds 1.4 V. Since this latch is "set dominant", it cannot be reset until either of these signals is removed and, the voltage at $C_{\text{Soft-Start}}$ is less than 1.0 V.

PWM Comparator and Latch

A PWM circuit typically compares an error voltage with a ramp signal. The outcome of this comparison determines the state of the output. In voltage mode operation the ramp signal is the voltage ramp of the timing capacitor. In current mode operation the ramp signal is the voltage ramp induced in a current sensing element. The ramp input of the PWM comparator is pinned out so that the user can decide which mode of operation best suits the application requirements. The ramp input has a 1.25 V offset such that whenever the voltage at this pin exceeds the error amplifier output voltage minus 1.25 V, the PWM comparator will cause the PWM latch to set, disabling the outputs. Once the PWM latch is set, only a blanking pulse by the oscillator can reset it, thus initiating the next cycle.

Current Limiting and Shutdown

A pin is provided to perform current limiting and shutdown operations. Two comparators are connected to the input of this pin. The reference voltage for the current limit comparator is not set internally. A pin is provided so the user can set the voltage. When the voltage at the current limit input pin exceeds the externally set voltage, the PWM latch is set, disabling the output. In this way cycle-by-cycle current limiting is accomplished. If a current limit resistor is used in series with the power devices, the value of the resistor is found by:

$$R_{\text{Sense}} = \frac{I_{\text{Limit Reference Voltage}}}{I_{\text{pk(} \text{switch)}}$$

If the voltage at this pin exceeds 1.4 V, the second comparator is activated. This comparator sets a latch which, in turn, causes the soft start capacitor to be discharged. In this way a "hiccup" mode of recovery is possible in the case of output short circuits. If a current limit resistor is used in series with the output devices, the peak current at which the controller will enter a "hiccup" mode is given by:

$$I_{\text{shutdown}} = \frac{1.4 \text{ V}}{R_{\text{Sense}}}$$

Undervoltage Lockout

There are two undervoltage lockout circuits within the IC. The first senses V_{CC} and the second V_{ref} . During power-up, V_{CC} must exceed 9.2 V and V_{ref} must exceed 4.0 before the outputs can be enabled and the Soft-Start latch released. If V_{CC} falls below 8.4 V or V_{ref} falls below 3.6 V, the outputs are disabled and the soft start latch is activated. When the UVLO is active, the part is in a low current standby mode allowing the IC to have an off-line bootstrap start-up circuit. Typical start-up current is 400 μ A.

Output

The MC34023 has a high current totem pole output specifically designed for direct drive of power MOSFETs. They are capable of up to ± 2.0 A peak drive current with a typical rise and fall time of 30 ns driving a 1.0 nF load.

Separate pins for V_C and Power Ground are provided. With proper implementation, a significant reduction of switching transient noise imposed on the control circuitry is possible. The separate V_C supply input also allows the designer added flexibility in tailoring the drive voltage independent of V_{CC} .

Reference

A 5.1 V bandgap reference is pinned out and is trimmed to an initial accuracy of $\pm 1.0\%$ at 25°C. This reference has short circuit protection and can source in excess of 10 mA for powering additional control system circuitry.

Design Considerations

Do not attempt to construct the converter on wire-wrap or plug-in prototype boards. With high frequency, high power, switching power supplies it is imperative to have separate current loops for the signal paths and for the power paths. The printed circuit layout should contain a ground plane with low current signal and high current switch and output grounds returning on separate paths back to the input filter capacitor. Shown in Figure 35 is a printed circuit layout of the application circuit. Note how the power and ground traces are run. All bypass capacitors and snubbers should be connected as close as possible to the specific part in question. The PC board lead lengths must be less than 0.5 inches for effective bypassing for snubbing.

Instabilities

In current mode control, an instability can be encountered at any given duty cycle. The instability is caused by the current feedback loop. It has been shown that the instability is caused by a double pole at half the switching frequency. If an external ramp (S_e) is added to the on-time ramp (S_n) of the current-sense waveform, stability can be achieved (see Figure 20).

One must be careful not to add too much ramp compensation. If too much is added the system will start to perform like a voltage mode regulator. All benefits of current mode control will be lost. Figure 25 is an example of one way in which external ramp compensation can be implemented.

Figure 20. Ramp Compensation

3

A simple equation can be used to calculate the amount of external ramp necessary to add that will achieve stability in the current loop. For the following equations, the calculated values for the application circuit in Figure 34 are also shown.

$$S_e = \frac{V_{sec}(\partial_{(max)} - 0.18)A_i}{L}$$

where: V_{sec} = minimum voltage at the input of the output inductor

$\partial_{(max)}$ = maximum duty cycle

A_i = gain of the current sense network (see Figures 23, 24, and 25)

L = output inductor

For the application circuit: $S_e = \frac{7(0.8 - 0.18)0.075}{1.8 \mu} = 18 \cdot 10^4$

As a sanity check, the modulator gain of the circuit can be calculated by:

$$m_{c1} = 1 + \frac{S_e/S_n}{\frac{di}{dt} A_i}$$

where: di = output inductor slope

dt = maximum on time

A_i = gain of the current sense network

(see Figures 25, 26, 27).

For the application circuit:

$$S_n = \frac{3.0}{0.8 \cdot 10^6} \cdot 0.075 = 22.5 \cdot 10^4$$

$$m_{c1} = 1 + \frac{18 \cdot 10^4}{22.5 \cdot 10^4} = 1.8$$

This can be compared against the maximum modulator gain necessary to make the system immune to audio susceptibility tests:

$$m_{c2} = \frac{2 - \partial}{2\partial'}, \text{ where: } \partial = \text{max duty cycle}$$

$$\partial' = 1 - \text{max duty cycle}$$

For the application circuit: $m_{c2} = \frac{2 - 0.8}{2(0.2)} = 3$, m_{c2} should be larger than m_{c1} .

MC34023, MC33023

PIN FUNCTION DESCRIPTION

3

Pin		Function	Description
DIP/SOIC	PLCC		
1	2	Error Amp Inverting Input	This pin is usually used for feedback from the output of the power supply.
2	3	Error Amp Noninverting Input	This pin is used to provide a reference in which an error signal can be produced on the output of the error amp. Usually this is connected to V_{ref} , however an external reference can also be used.
3	4	Error Amp Output	This pin is provided for compensating the error amp for poles and zeros encountered in the power supply system, mostly the output LC filter.
4	5	Clock	This is a bidirectional pin used for synchronization.
5	7	R_T	The value of R_T sets the charge current through timing Capacitor, C_T .
6	8	C_T	In conjunction with R_T , the timing Capacitor sets the switching frequency. Because this part is a push-pull output, each output runs at one-half the frequency set at this pin.
7	9	Ramp Input	For voltage mode operation this pin is connected to C_T . For current mode operation this pin is connected through a filter to the current sensing element.
8	10	Soft-Start	A capacitor at this pin sets the Soft-Start time.
9	12	Current Limit/Shutdown	This pin has two functions. First, it provides cycle-by-cycle current limiting. Second, if the current is excessive, this pin will reinitiate a Soft-Start cycle.
10	13	Ground	This pin is the ground for the control circuitry.
11	14	Current Limit Reference Input	This is a high current dual totem pole output.
12	15	Power Ground	This is a separate power ground return that is connected back to the power source. It is used to reduce the effects of switching transient noise on the control circuitry.
13	17	V_C	This is a separate power source connection for the outputs that is connected back to the power source input. With a separate power source connection, it can reduce the effects of switching transient noise on the control circuitry.
14	18	Output	This is a high current dual totem pole output.
15	19	V_{CC}	This pin is the positive supply of the control IC.
16	20	V_{ref}	This is a 5.0 V reference. It is usually connected to the noninverting input of the error amplifier.

Figure 21. Voltage Mode Operation

In voltage mode operation, the control range on the output of the Error Amplifier from 0% to 90% duty cycle is from 2.25 V to 4.05 V.

Figure 22. Current Mode Operation

In current mode control, an RC filter should be placed at the ramp input to filter the leading edge spike caused by turn-on of a power MOSFET.

MC34023, MC33023

Figure 23. Resistive Current Sensing

The addition of an RC filter will eliminate instability caused by the leading edge spike on the current waveform. This sense signal can also be used at the ramp input pin for current mode control. For ramp compensation it is necessary to know the gain of the current feedback loop. If a transformer is used, the gain can be calculated by:

$$A_i = \frac{R_{Sense}}{\text{turns ratio}}$$

Figure 24. Primary Side Current Sensing

The addition of an RC filter will eliminate instability caused by the leading edge spike on the current waveform. This sense signal can also be used at the ramp input pin for current mode control. For ramp compensation it is necessary to know the gain of the current feedback loop. The gain can be calculated by:

$$A_i = \frac{R_w}{\text{turns ratio}}$$

3

Figure 25A. Slope Compensation (Noise Sensitive)

This method of slope compensation is easy to implement, however, it is noise sensitive. Capacitor C_1 provides AC coupling. The oscillator signal is added to the current signal by a voltage divider consisting of resistors R_1 and R_2 .

Figure 25B. Slope Compensation (Noise Immune)

When only one output, this method of slope compensation can be used and it is relatively noise immune. Resistor R_M and capacitor C_M provide the added slope necessary. By choosing R_M and C_M with a larger time constant than the switching frequency, you can assume that its charge is linear. First choose C_M , then R_M can be adjusted to achieve the required slope. The diode provides a reset pulse the ramp inputs at the end of every cycle. The charge current I_M can be calculated by $I_M = C_M S_e$. Then R_M can be calculated by $R_M = V_{CC}/I_M$

MC34023, MC33023

3

Figure 26. Dead Time Addition

Additional dead time can be added by the addition of a dead time resistor from V_{ref} to C_T . See text on Oscillator section for more information.

Figure 27. External Clock Synchronization

The sync pulse fed into the clock pin must be at least 3.9 V. R_T and C_T need to be set 10% slower than the sync frequency. This circuit is also used in Voltage Mode operation for master/slave operation. The clock signal would be coming from the master which is set at the desired operating frequency, while the slave is set 10% slower.

Figure 28. Master/Slave Operation Over Short Distances

Figure 29. Master/Slave Operation Over Long Distances

Figure 30. Buffered Maximum Clamp Level

In voltage mode operation, the maximum duty cycle can be clamped. By the addition of a PNP transistor to buffer the clamp voltage, the Soft-Start current is not affected by R_1 .

The new equation for Soft-Start is $t = \frac{V_{clamp} + 0.6}{9.0 \mu A} (C_{SS})$

In current mode operation, this circuit will limit the maximum voltage allowed at the ramp input to end a cycle.

Figure 31. Bipolar Transistor Drive

A series gate resistor may be needed to dampen high frequency parasitic oscillation caused by the MOSFET's input capacitance and any series wiring inductance in the gate-source circuit. The series resistor will also decrease the MOSFET switching speed. A Schottky diode can reduce the driver's power dissipation due to excessive ringing, by preventing the output pin from being driven below ground. The Schottky diode also prevents substrate injection when the output pin is driven below ground.

Figure 32. MOSFET Parasitic Oscillations

The totem pole output can furnish negative base current for enhanced transistor turn-off, with the addition of the capacitor in series with the base.

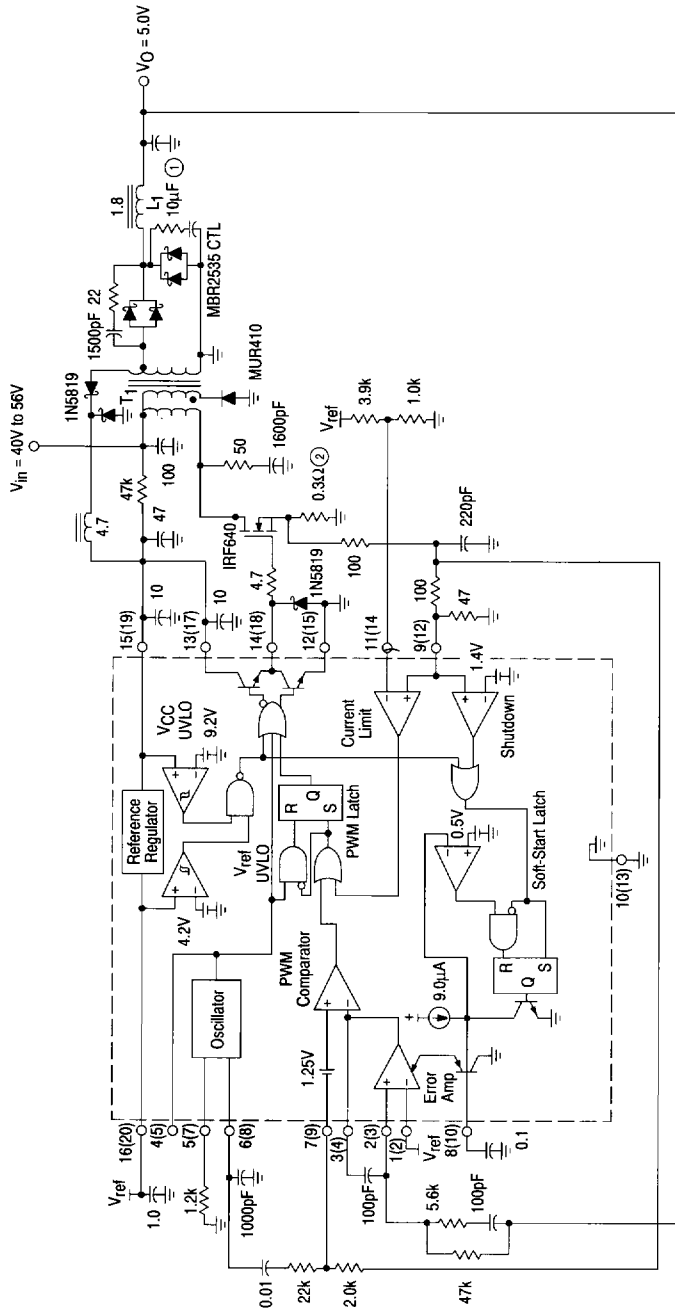

Figure 33. Isolated MOSFET Drive

The totem pole output can easily drive pulse transformers. A Schottky diode is recommended when driving inductive loads at high frequencies. The diode can reduce the driver's power dissipation due to excessive ringing, by preventing the output pin from being driven below ground.

Colicraft P3270-A

- Heatsinks — Power FET: Aavid Heatsink #533902B02554 with clip
- Output Rectifiers: Aavid Heatsink #533402B02552 with clip
- Insulators — All power devices are insulated with Berquist Sil-Pad 150
- Ā — 10(1.0 μF) ceramic capacitors in parallel
- Á — 5(1.5 Ω) resistors in parallel

Test	Condition	Results
Line Regulation	V _{in} = 40 V to 56 V, I _O = 7.5 A	14 mV ± 0.275%
Load Regulation	V _{in} = 48 V, I _O = 4.0 A to 7.5 A	54 mV ± 1.0%
Output Ripple	V _{in} = 48 V, I _O = 7.5 A	100 mVp-p
Efficiency	V _{in} = 48 V, I _O = 7.5 A	69.8%

MC34023, MC33023
