1K X24C01A 128 x 8 Bit

Serial E²PROM

FEATURES

- 2.7V to 5.5V Power Supply
- Low Power CMOS
  - —Active Current Less Than 1 mA
  - —Standby Current Less Than 50 µA
- Internally Organized 128 x 8
- Self Timed Write Cycle
  - —Typical Write Cycle Time of 5 ms
- 2 Wire Serial Interface
  - —Bidirectional Data Transfer Protocol
- Four Byte Page Write Operation
  - —Minimizes Total Write Time Per Byte
- High Reliability
  - —Endurance: 100,000 Cycles
  - —Data Retention: 100 Years
- New Hardwire – Write Control Function

DESCRIPTION

The X24C01A is a CMOS 1024 bit serial E²PROM, internally organized 128 x 8. The X24C01A features a serial interface and software protocol allowing operation on a simple two wire bus. Three address inputs allow up to eight devices to share a common two wire bus.

Xicor E²PROMs are designed and tested for applications requiring extended endurance. Inherent data retention is greater than 100 years. Available in an eight pin DIP and SOIC package.

FUNCTIONAL DIAGRAM

PIN DESCRIPTIONS

Serial Clock (SCL)
The SCL input is used to clock all data into and out of the device.

Serial Data (SDA)
SDA is a bidirectional pin used to transfer data into and out of the device. It is an open drain output and may be wire-ORed with any number of open drain or open collector outputs.

An open drain output requires the use of a pull-up resistor. For selecting typical values, refer to the Guidelines for Calculating Typical Values of Bus Pull-Up Resistors graph.

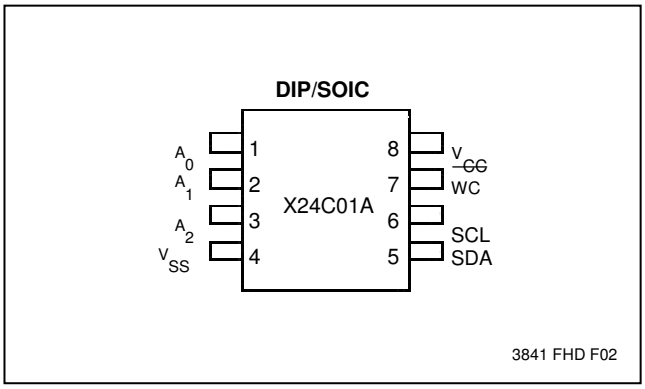
Address (A_0, A_1, A_2)
The address inputs are used to set the least significant three bits of the seven bit slave address. These inputs can be static or actively driven. If used statically they must be tied to V_{SS} or V_{CC} as appropriate. If actively driven, they must be driven to V_{SS} or to V_{CC}.

WRITE CONTROL (WC)
The Write Control input controls the ability to write to the device. When WC is LOW (tied to V_{SS}) the X24C01A will be enabled to perform write operations. When WC is HIGH (tied to V_{CC}) the internal high voltage circuitry will be disabled and all writes will be disabled.

DEVICE OPERATION

The X24C01A supports a bidirectional bus oriented protocol. The protocol defines any device that sends data onto the bus as a transmitter, and the receiving device as the receiver. The device controlling the transfer is a master and the device being controlled is the slave. The master will always initiate data transfers and provide the clock for both transmit and receive operations. Therefore, the X24C01A will be considered a slave in all applications.

PIN CONFIGURATION



PIN NAMES

Symbol	Description
A_0–A_2	Address Inputs
SDA	Serial Data
SCL	Serial Clock
WC	Write Control
V_{SS}	Ground
V_{CC}	+5V

3841 PGM T01

Clock and Data Conventions
Data states on the SDA line can change only during SCL LOW. SDA state changes during SCL HIGH are reserved for indicating start and stop conditions. Refer to Figures 1 and 2.

Start Condition
All commands are preceded by the start condition, which is a HIGH to LOW transition of SDA when SCL is HIGH. The X24C01A continuously monitors the SDA and SCL lines for the start condition and will not respond to any command until this condition has been met.

Figure 1. Data Validity

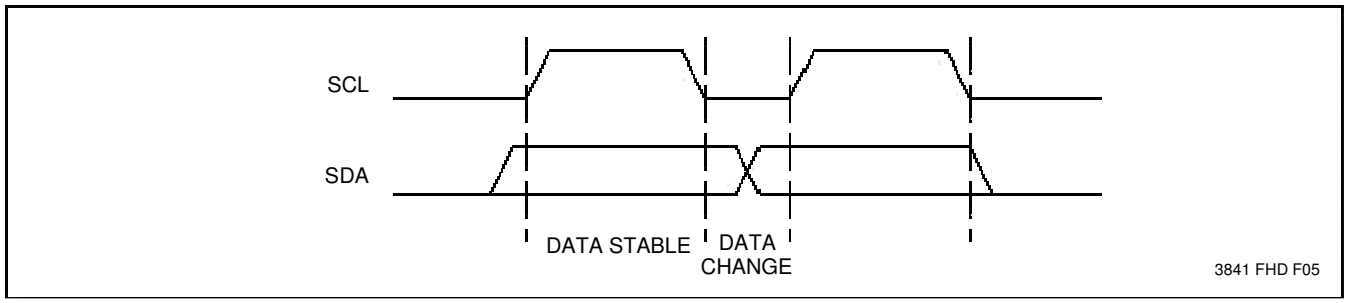


Figure 2. Definition of Start and Stop

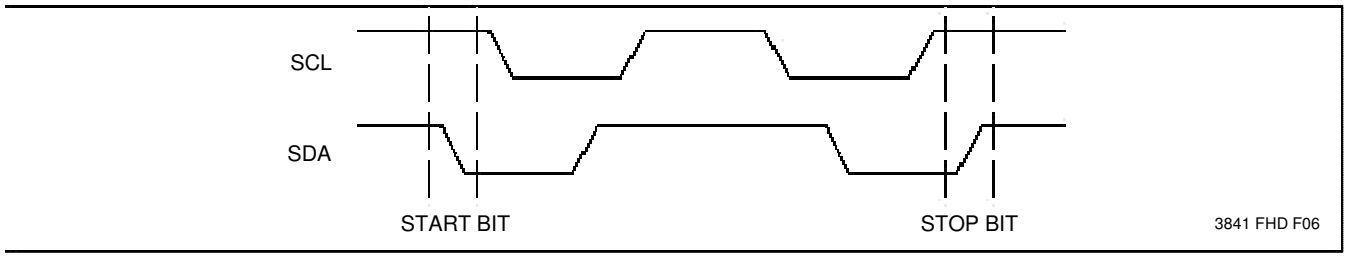


Stop Condition

All communications must be terminated by a stop condition, which is a LOW to HIGH transition of SDA when SCL is HIGH.

The stop condition is also used by the X24C01A to place the device into the standby power mode after a

read sequence. A stop condition can only be issued after the transmitting device has released the bus.

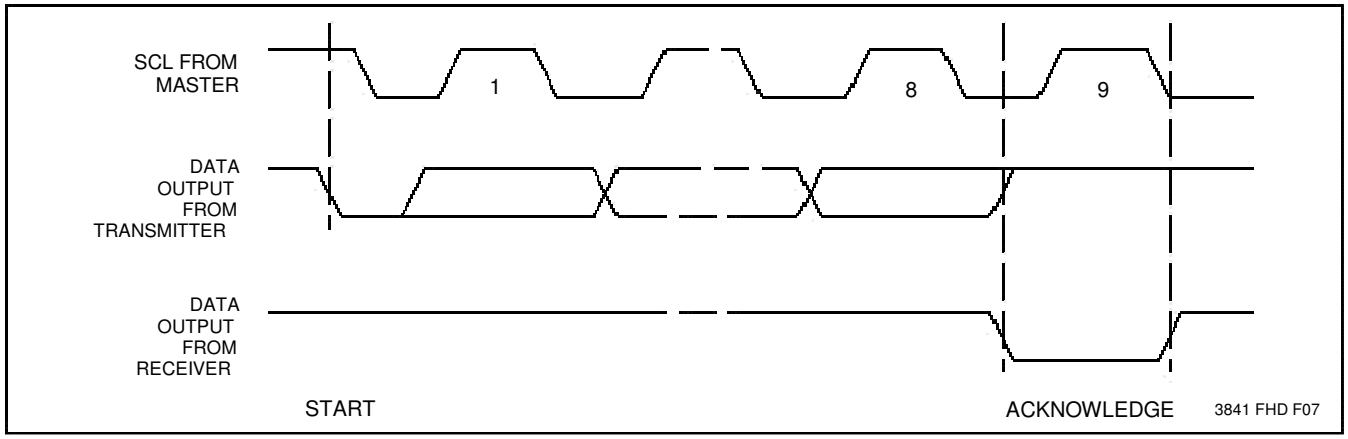
Acknowledge

Acknowledge is a software convention used to indicate successful data transfers. The transmitting device will release the bus after transmitting eight bits. During the ninth clock cycle the receiver will pull the SDA line LOW to acknowledge that it received the eight bits of data. Refer to Figure 3.

The X24C01A will respond with an acknowledge after recognition of a start condition and its slave address. If both the device and a write operation have been selected, the X24C01A will respond with an acknowledge after the receipt of each subsequent eight bit word.

In the read mode the X24C01A will transmit eight bits of data release the SDA line and monitor the line for an acknowledge. If an acknowledge is detected and no stop condition is generated by the master, the X24C01A will continue to transmit data. If an acknowledge is not detected, the X24C01A will terminate further data transmissions. The master must then issue a stop condition to return the X24C01A to the standby power mode and place the device into a known state.

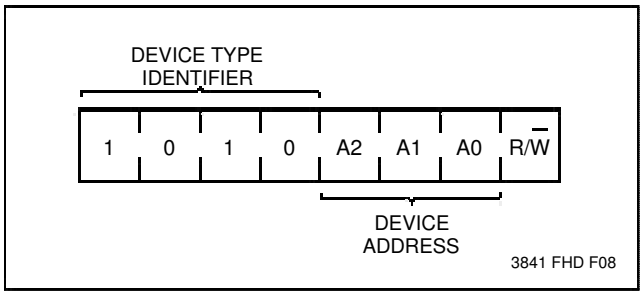
Figure 3. Acknowledge Response From Receiver



DEVICE ADDRESSING

Following a start condition the master must output the address of the slave it is accessing. The most significant four bits of the slave address are the device type identifier (see Figure 4). For the X24C01A this is fixed as 1010[B].

Figure 4. Slave Address



The next three significant bits address a particular device. A system could have up to eight X24C01A devices on the bus (see Figure 10). The eight addresses are defined by the state of the A_0, A_1 and A_2 inputs.

The last bit of the slave address defines the operation to be performed. When set to one a read operation is selected, when set to zero a write operation is selected.

Following the start condition, the X24C01A monitors the SDA bus comparing the slave address being transmitted with its slave address (device type and state of A_0, A_1 and A_2 inputs). Upon a correct compare the X24C01A outputs an acknowledge on the SDA line. Depending on the state of the R/W bit, the X24C01A will execute a read or write operation.

WRITE OPERATIONS

Byte Write

For a write operation, the X24C01A requires a second address field. This address field is the word address, comprised of eight bits, providing access to any one of the 128 words of memory. Note: the most significant bit is a don't care. Upon receipt of the word address the X24C01A responds with an acknowledge, and awaits the next eight bits of data, again responding with an acknowledge. The master then terminates the transfer by generating a stop condition, at which time the X24C01A begins the internal write cycle to the nonvolatile memory. While the internal write cycle is in progress the X24C01A inputs are disabled, and the device will not respond to any requests from the master. Refer to Figure 5 for the address, acknowledge and data transfer sequence.

Figure 5. Byte Write

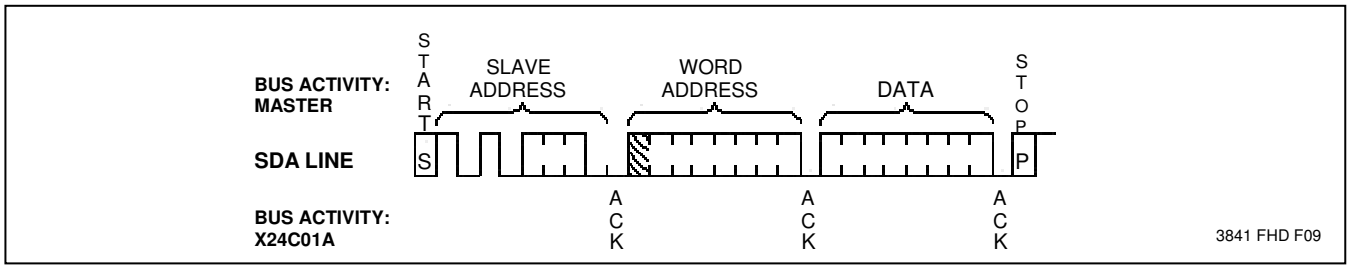


Figure 6. Page Write

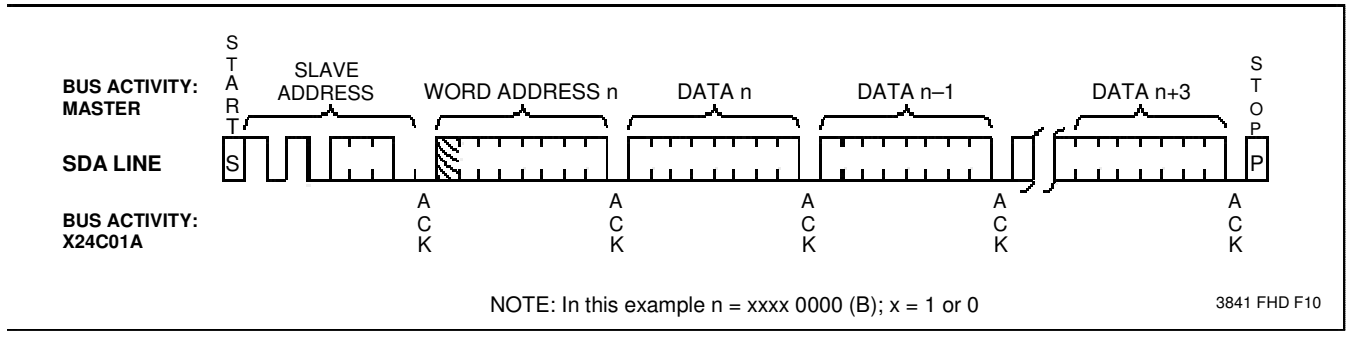


Page Write

The X24C01A is capable of an four byte page write operation. It is initiated in the same manner as the byte write operation, but instead of terminating the write cycle after the first data word is transferred, the master can transmit up to three more words. After the receipt of each word the X24C01A will respond with an acknowledge.

After the receipt of each word, the two low order address bits are internally incremented by one. The high order five bits of the address remain constant. If the master should transmit more than four words prior to generating the stop condition, the address counter will "roll over" and the previously written data will be overwritten. As with the byte write operation, all inputs are disabled until completion of the internal write cycle. Refer to Figure 6 for the address, acknowledge and data transfer sequence.

Acknowledge Polling

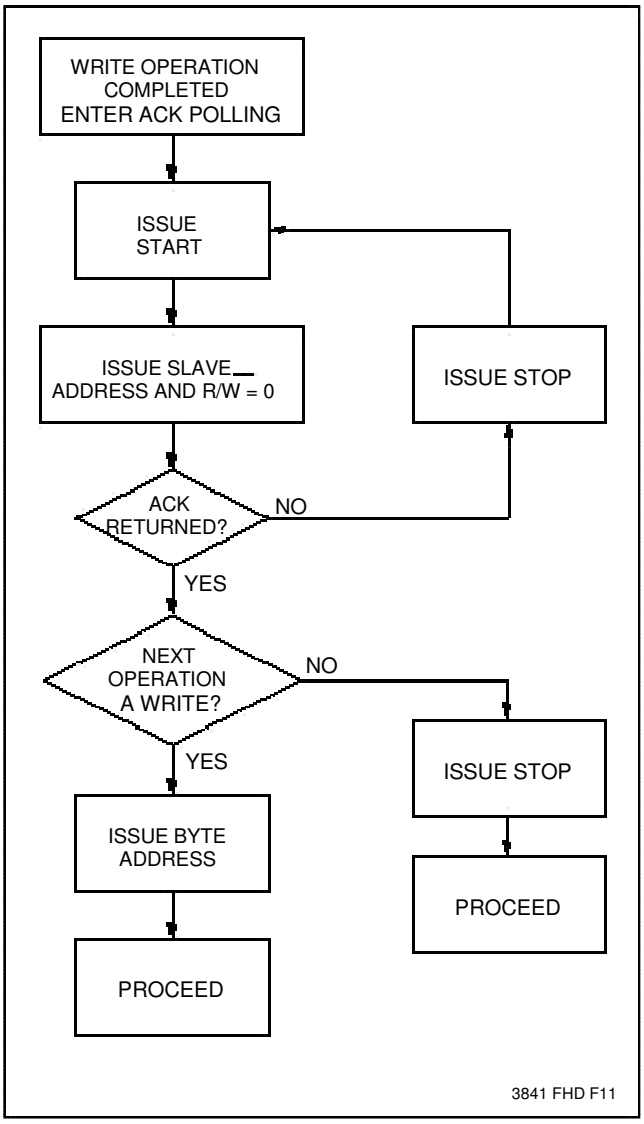
The disabling of the inputs, during the internal write operation, can be used to take advantage of the typical 5 ms write cycle time. Once the stop condition is issued to indicate the end of the host's write operation the X24C01A initiates the internal write cycle. ACK polling can be initiated immediately. This involves issuing the start condition followed by the slave address for a write operation. If the X24C01A is still busy with the write operation no ACK will be returned. If the X24C01A has completed the write operation an ACK will be returned and the master can then proceed with the next read or write operation (See Flow 1).

READ OPERATIONS

Read operations are initiated in the same manner as write operations with the exception that the R/W bit of the slave address is set to a one. There are three basic read operations: current address read, random read and sequential read.

It should be noted that the ninth clock cycle of the read operation is not a "don't care." To terminate a read operation, the master must either issue a stop condition during the ninth cycle or hold SDA HIGH during the ninth clock cycle and then issue a stop condition.

Flow 1. ACK Polling Sequence



Current Address Read

Internally the X24C01A contains an address counter that maintains the address of the last word accessed, incremented by one. Therefore, if the last access (either a read or write) was to address n, the next read operation would access data from address n + 1. Upon receipt of the slave address with R/W set to one, the X24C01A issues an acknowledge and transmits the eight bit word during the next eight clock cycles. The read operation is terminated by the master; by not responding with an acknowledge and by issuing a stop condition. Refer to Figure 7 for the sequence of address, acknowledge and data transfer.

Random Read

Random read operations allow the master to access any memory location in a random manner. Prior to issuing the slave address with the R/W bit set to one, the master must first perform a “dummy” write operation. The master issues issues the start condition, and the slave address followed by the word address it is to read. After the word address acknowledge, the master immediately reissues the start condition and the slave address with the R/W bit set to one. This will be followed by an acknowledge from the X24C01A and then by the eight bit word. The read operation is terminated by the master; by not responding with an acknowledge and by issuing a stop condition.

Refer to Figure 8 for the address, acknowledge and data transfer sequence.

Figure 7. Current Address Read

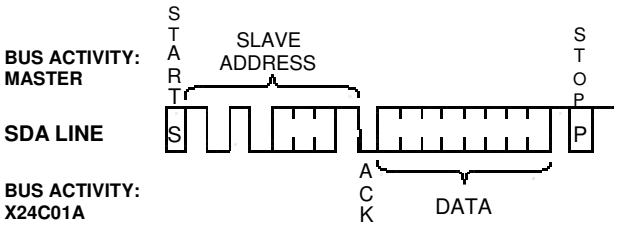


Figure 8. Random Read

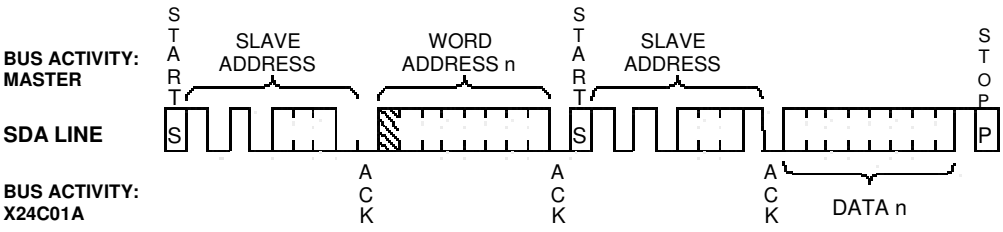

Sequential Read

Sequential Read can be initiated as either a current address read or random access read. The first word is transmitted as with the other modes, however, the master now responds with an acknowledge, indicating it requires additional data. The X24C01A continues to output data for each acknowledge received. The read operation is terminated by the master, by not responding with an acknowledge and by issuing a stop condition.

The data output is sequential, with the data from address n followed by the data from n + 1. The address counter for read operations increments all address bits, allowing the entire memory contents to be serially read during one operation. At the end of the address space (address 127) the counter "rolls over" to address 0 and the X24C01A continues to output data for each acknowledge received. Refer to Figure 9 for the address, acknowledge and data transfer sequence.

Figure 9. Sequential Read

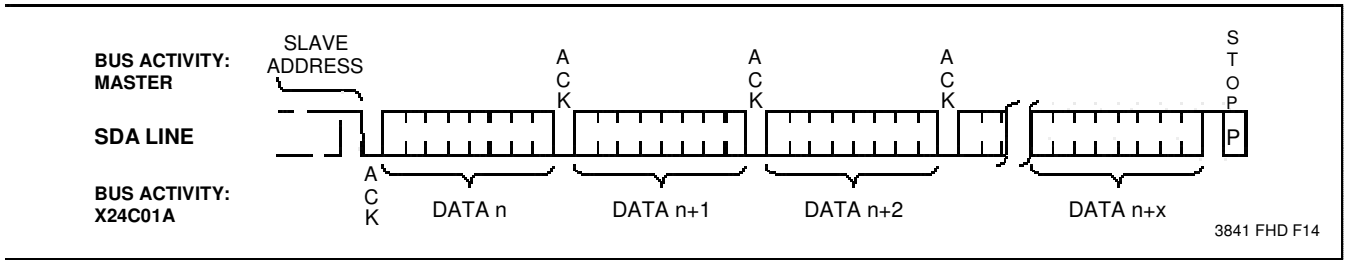

Figure 10. Typical System Configuration

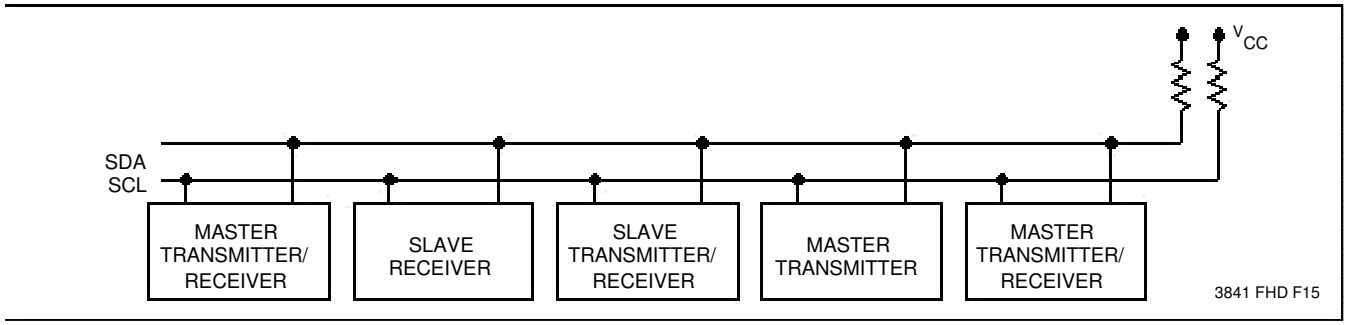

ABSOLUTE MAXIMUM RATINGS*

Temperature Under Bias ..... –65°C to +135°C
Storage Temperature ..... –65°C to +150°C
Voltage on any Pin with
Respect to V_{SS} ..... –1.0V to +7V
D.C. Output Current ..... 5 mA
Lead Temperature (Soldering,
10 Seconds) ..... 300°C

***COMMENT**

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device.

This is a stress rating only and the functional operation of the device at these or any other conditions above those

indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

RECOMMENDED OPERATING CONDITIONS

Temperature	Min.	Max.
Commercial	0°C	70°C
Industrial	–40°C	+85°C
Military	–55°C	+125°C

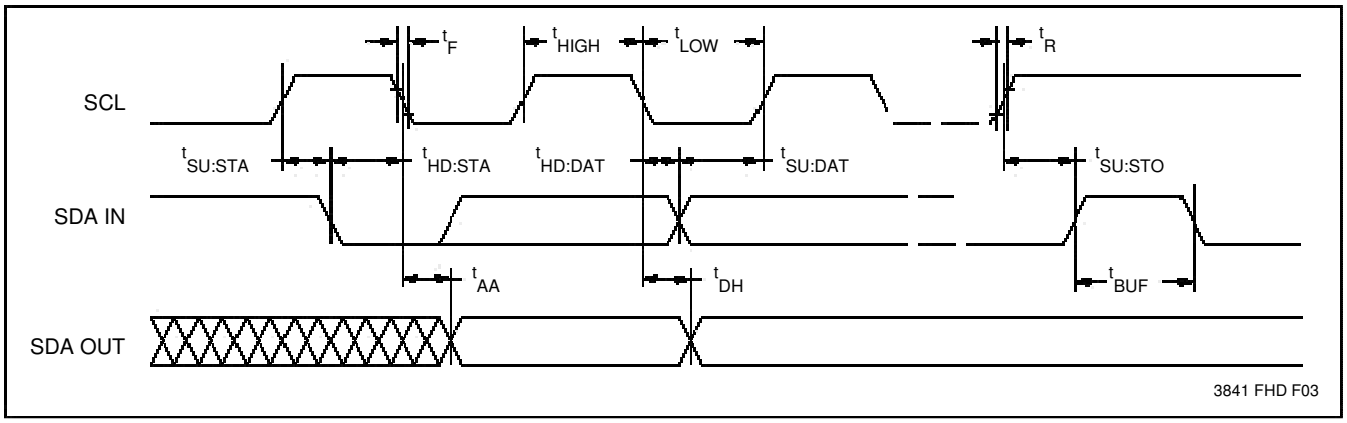
POWER-UP TIMING

Symbol	Parameter	Max.	Units
t_{PUR}(4)	Power-Up to Read Operation	1	ms
t_{PUW}(4)	Power-Up to Write Operation	5	ms

3841 PGM T09

Bus Timing



Note: (4)t_{PUR} and t_{PUW} are the delays required from the time V_{CC} is stable until the specified operation can be initiated. These parameters are periodically sampled and not 100% tested.

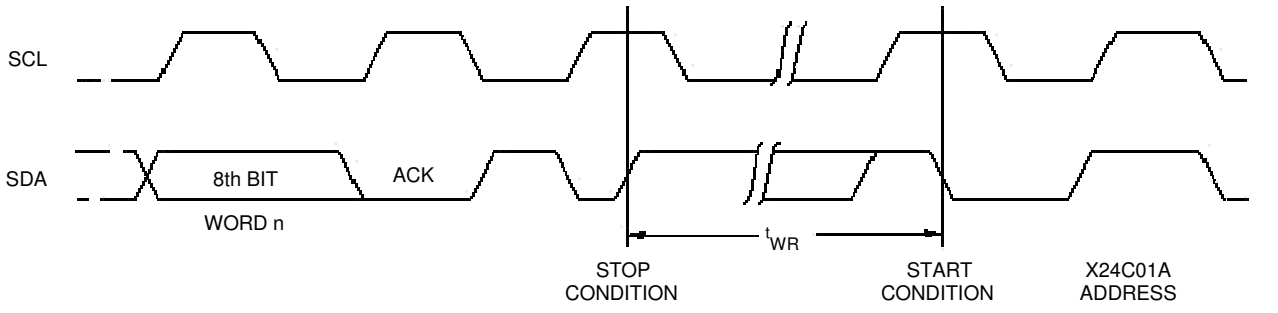
WRITE CYCLE LIMITS

Symbol	Parameter	Min.	Typ.(5)	Max.	Units
t_{WR}(6)	Write Cycle Time		5	10	ms

3841 PGM T10

The write cycle time is the time from a valid stop condition of a write sequence to the end of the internal erase/program cycle. During the write cycle, the X24C01A bus interface circuits are disabled, SDA is allowed to remain high, and the device does not respond to its slave address.

Write Cycle Timing



Notes:(5) Typical values are for T_A = 25°C and nominal supply voltage (5V).

(6) t_{WR} is the minimum cycle time from the system perspective when polling techniques are not used. It is the maximum time the device requires to perform the internal write operation.

Guidelines for Calculating Typical Values of Bus Pull-Up Resistors
