CY7C1311V18
CY7C1313V18
CY7C1315V18

18-Mb QDR™-II SRAM 4-Word Burst Architecture

Features

- Separate Independent Read and Write Data Ports
 - Supports concurrent transactions
- 250-MHz Clock for High Bandwidth
- Four-word Burst for reducing address bus frequency
- Double Data Rate (DDR) interfaces on both Read and Write Ports (data transferred at 500 MHz) at 250 MHz
- Two input clocks (K and \bar{K}) for precise DDR timing
 - SRAM uses rising edges only
- Two output clocks (C and \bar{C}) accounts for clock skew and flight time mismatches
- Echo clocks (CQ and \bar{CQ}) simplify data capture in high speed systems
- Single multiplexed address input bus latches address inputs for both Read and Write ports
- Separate Port Selects for depth expansion
- Synchronous internally self-timed writes
- Available in $\times 8$, $\times 18$, and $\times 36$ configurations
- 1.8V core power supply with HSTL Inputs and Outputs
- 13 \times 15 mm 1.0-mm pitch FBGA package, 165-ball (11 \times 15 matrix)
- Variable drive HSTL output buffers
- Expanded HSTL output voltage (1.4V–1.9V)
- JTAG Interface
- On-chip Delay Lock Loop (DLL)

Configurations

CY7C1311V18–2M \times 8

CY7C1313V18–1M \times 18

CY7C1315V18–512K \times 36

Functional Description

The CY7C1311V18/CY7C1313V18/CY7C1315V18 are 1.8V Synchronous Pipelined SRAMs, equipped with QDR™-II architecture. QDR-II architecture consists of two separate ports to access the memory array. The Read port has dedicated Data Outputs to support Read operations and the Write Port has dedicated Data Inputs to support Write operations. QDR-II architecture has separate data inputs and data outputs to completely eliminate the need to “turn-around” the data bus required with common I/O devices. Access to each port is accomplished through a common address bus. Addresses for Read and Write addresses are latched on alternate rising edges of the input (K) clock. Accesses to the QDR-II Read and Write ports are completely independent of one another. In order to maximize data throughput, both Read and Write ports are equipped with Double Data Rate (DDR) interfaces. Each address location is associated with four 8-bit words (CY7C1311V18) or 18-bit words (CY7C1313V18) or 36-bit words (CY7C1315V18) that burst sequentially into or out of the device. Since data can be transferred into and out of the device on every rising edge of both input clocks (K/ \bar{K} and C/ \bar{C}), memory bandwidth is maximized while simplifying system design by eliminating bus “turn-arounds”.

Depth expansion is accomplished with Port Selects for each port. Port selects allow each port to operate independently.

All synchronous inputs pass through input registers controlled by the K or \bar{K} input clocks. All data outputs pass through output registers controlled by the C or \bar{C} input clocks. Writes are conducted with on-chip synchronous self-timed write circuitry.

Pin Definitions

Pin Name	I/O	Pin Description
D _[x:0]	Input-Synchronous	Data input signals, sampled on the rising edge of K and \bar{K} clocks during valid write operations. CY7C1311V18 – D _[7:0] CY7C1313V18 – D _[17:0] CY7C1315V18 – D _[35:0]
WPS	Input-Synchronous	Write Port Select, active LOW. Sampled on the rising edge of the K clock. When asserted active, a write operation is initiated. Deasserting will deselect the Write port. Deselecting the Write port will cause D _[x:0] to be ignored.
$\overline{BWS_0}$, $\overline{BWS_1}$, $\overline{BWS_2}$, $\overline{BWS_3}$	Input-Synchronous	Byte Write Select 0, 1, 2 and 3 – active LOW. Sampled on the rising edge of the K and \bar{K} clocks during write operations. Used to select which byte is written into the device during the current portion of the write operations. Bytes not written remain unaltered. CY7C1311V18 – $\overline{BWS_0}$ controls D _[3:0] and $\overline{BWS_1}$ controls D _[7:4] . CY7C1313V18 – $\overline{BWS_0}$ controls D _[8:0] and $\overline{BWS_1}$ controls D _[17:9] . CY7C1315V18 – $\overline{BWS_0}$ controls D _[8:0] , $\overline{BWS_1}$ controls D _[17:9] , $\overline{BWS_2}$ controls D _[26:18] and $\overline{BWS_3}$ controls D _[35:27] . All the byte writes are sampled on the same edge as the data. Deselecting a Byte Write Select will cause the corresponding byte of data to be ignored and not written into the device.
A	Input-Synchronous	Address Inputs. Sampled on the rising edge of the K clock during active read and write operations. These address inputs are multiplexed for both Read and Write operations. Internally, the device is organized as 2M x 8 (4 arrays each of 512K x 8) for CY7C1311V18, 1M x 18 (4 arrays each of 256K x 18) for CY7C1313V18 and 256K x 36 (4 arrays each of 128K x 36) for CY7C1315V18. Therefore, only 19 address inputs are needed to access the entire memory array of CY7C1311V18, 18 address inputs for CY7C1313V18 and 17 address inputs for CY7C1315V18. These inputs are ignored when the appropriate port is deselected.

Pin Definitions (continued)

Pin Name	I/O	Pin Description
Q _[x:0]	Outputs-Synchronous	Data Output signals. These pins drive out the requested data during a Read operation. Valid data is driven out on the rising edge of both the C and \bar{C} clocks during Read operations or K and \bar{K} , when in single clock mode. When the Read port is deselected, Q _[x:0] are automatically three-stated. CY7C1311V18 – Q _[7:0] CY7C1313V18 – Q _[17:0] CY7C1315V18 – Q _[35:0]
RPS	Input-Synchronous	Read Port Select, active LOW. Sampled on the rising edge of Positive Input Clock (K). When active, a Read operation is initiated. Deasserting will cause the Read port to be deselected. When deselected, the pending access is allowed to complete and the output drivers are automatically three-stated following the next rising edge of the C clock. Each read access consists of a burst of four sequential transfers.
C	Input-Clock	Positive Output Clock Input. C is used in conjunction with \bar{C} to clock out the Read data from the device. C and \bar{C} can be used together to deskew the flight times of various devices on the board back to the controller. See application example for further details.
\bar{C}	Input-Clock	Negative Output Clock Input. \bar{C} is used in conjunction with C to clock out the Read data from the device. C and \bar{C} can be used together to deskew the flight times of various devices on the board back to the controller. See application example for further details.
K	Input-Clock	Positive Input Clock Input. The rising edge of K is used to capture synchronous inputs to the device and to drive out data through Q _[x:0] when in single clock mode. All accesses are initiated on the rising edge of K.
\bar{K}	Input-Clock	Negative Input Clock Input. \bar{K} is used to capture synchronous inputs being presented to the device and to drive out data through Q _[x:0] when in single clock mode.
CQ	Echo Clock	CQ is referenced with respect to C. This is a free running clock and is synchronized to the output clock of the QDR-II. In the single clock mode, CQ is generated with respect to K. The timings for the echo clocks are shown in the AC timing table.
$\bar{C}Q$	Echo Clock	$\bar{C}Q$ is referenced with respect to \bar{C}. This is a free running clock and is synchronized to the output clock of the QDR-II. In the single clock mode, $\bar{C}Q$ is generated with respect to K. The timings for the echo clocks are shown in the AC timing table.
ZQ	Input	Output Impedance Matching Input. This input is used to tune the device outputs to the system data bus impedance. Q _[x:0] output impedance are set to 0.2 x RQ, where RQ is a resistor connected between ZQ and ground. Alternately, this pin can be connected directly to V _{DD} , which enables the minimum impedance mode. This pin cannot be connected directly to GND or left unconnected.
DOFF	Input	DLL Turn Off. Connecting this pin to ground will turn off the DLL inside the device. The timings in the DLL turned off operation will be different from those listed in this data sheet. More details on this operation can be found in the application note, "DLL Operation in the QDR-II."
TDO	Output	TDO for JTAG.
TCK	Input	TCK pin for JTAG.
TDI	Input	TDI pin for JTAG.
TMS	Input	TMS pin for JTAG.
NC	Input	No connects inside the package. Can be tied to any voltage level.
NC/36M	Input	Address expansion for 36M. This is not connected to the die and so can be tied to any voltage level.
NC/72M	Input	Address expansion for 72M. This is not connected to the die and so can be tied to any voltage level.
V _{SS} /72M	Input	Address expansion for 72M. This must be tied LOW on the these devices.
V _{SS} /144M	Input	Address expansion for 144M. This must be tied LOW on the these devices.
V _{SS} /288M	Input	Address expansion for 288M. This must be tied LOW on the these devices.

Pin Definitions (continued)

Pin Name	I/O	Pin Description
V _{REF}	Input-Reference	Reference Voltage Input. Static input used to set the reference level for HSTL inputs and Outputs as well as AC measurement points.
V _{DD}	Power Supply	Power supply inputs to the core of the device. Should be connected to 1.8V power supply.
V _{SS}	Ground	Ground for the device. Should be connected to ground of the system.
V _{DDQ}	Power Supply	Power supply inputs for the outputs of the device. Should be connected to 1.5V power supply.

Introduction

Functional Overview

The CY7C1311V18/CY7C1313V18/CY7C1315V18 are synchronous pipelined Burst SRAMs equipped with both a Read Port and a Write Port. The Read port is dedicated to Read operations and the Write Port is dedicated to Write operations. Data flows into the SRAM through the Write port and out through the Read Port. These devices multiplex the address inputs in order to minimize the number of address pins required. By having separate Read and Write ports, the QDR-II completely eliminates the need to “turn-around” the data bus and avoids any possible data contention, thereby simplifying system design. Each access consists of four 8-bit data transfers in the case of CY7C1311V18, four 18-bit data transfers in the case of CY7C1313V18, and four 36-bit data in the case of CY7C1315V18 transfers in two clock cycles.

Accesses for both ports are initiated on the Positive Input Clock (K). All synchronous input timing is referenced from the rising edge of the input clocks (K and \bar{K}) and all output timing is referenced to the output clocks (C and \bar{C} or K and \bar{K} when in single clock mode).

All synchronous data inputs (D_[x:0]) inputs pass through input registers controlled by the input clocks (K and \bar{K}). All synchronous data outputs (Q_[x:0]) outputs pass through output registers controlled by the rising edge of the output clocks (C and \bar{C} or K and \bar{K} when in single-clock mode).

All synchronous control (\overline{RPS} , \overline{WPS} , $\overline{BWS}_{[x:0]}$) inputs pass through input registers controlled by the rising edge of the input clocks (K and \bar{K}).

The following descriptions take CY7C1313V18 as an example. However, the same is true for the other QDR-II SRAMs, CY7C1311V18 and CY7C1315V18.

These chips utilize a Delay Lock Loop (DLL) that is designed to function between 80 MHz and the specified maximum clock frequency. The DLL may be disabled by applying ground to the DOFF pin.

Read Operations

The CY7C1313V18 is organized internally as a 256K x 72 SRAM. Accesses are completed in a burst of four sequential 18-bit data words. Read operations are initiated by asserting \overline{RPS} active at the rising edge of the Positive Input Clock (K). The address presented to Address inputs are stored in the Read address register. Following the next K clock rise, the corresponding lowest order 18-bit word of data is driven onto the Q_[17:0] using \bar{C} as the output timing reference. On the subsequent rising edge of C the next 18-bit data word is driven onto the Q_[17:0]. This process continues until all four 18-bit data words have been driven out onto Q_[17:0]. The requested data will be valid 0.35 ns from the rising edge of the output clock (C

or \bar{C} , 250-MHz device). In order to maintain the internal logic, each read access must be allowed to complete. Each Read access consists of four 18-bit data words and takes 2 clock cycles to complete. Therefore, Read accesses to the device can not be initiated on two consecutive K clock rises. The internal logic of the device will ignore the second Read request. Read accesses can be initiated on every other K clock rise. Doing so will pipeline the data flow such that data is transferred out of the device on every rising edge of the output clocks (C and \bar{C} or K and \bar{K} when in single-clock mode).

When the read port is deselected, the CY7C1313V18 will first complete the pending read transactions. Synchronous internal circuitry will automatically three-state the outputs following the next rising edge of the Positive Output Clock (C). This will allow for a seamless transition between devices without the insertion of wait states in a depth expanded memory.

Write Operations

Write operations are initiated by asserting \overline{WPS} active at the rising edge of the Positive Input Clock (K). On the following K clock rise the data presented to D_[17:0] is latched and stored into the lower 18-bit Write Data register, provided $\overline{BWS}_{[1:0]}$ are both asserted active. On the subsequent rising edge of the Negative Input Clock (\bar{K}) the information presented to D_[17:0] is also stored into the Write Data Register, provided $\overline{BWS}_{[1:0]}$ are both asserted active. This process continues for one more cycle until four 18-bit words (a total of 72 bits) of data are stored in the SRAM. The 72 bits of data are then written into the memory array at the specified location. Therefore, Write accesses to the device can not be initiated on two consecutive K clock rises. The internal logic of the device will ignore the second Write request. Write accesses can be initiated on every other rising edge of the Positive Input Clock (K). Doing so will pipeline the data flow such that 18 bits of data can be transferred into the device on every rising edge of the input clocks (K and \bar{K}).

When deselected, the write port will ignore all inputs after the pending Write operations have been completed.

Byte Write Operations

Byte Write operations are supported by the CY7C1313V18. A write operation is initiated as described in the Write Operation section above. The bytes that are written are determined by \overline{BWS}_0 and \overline{BWS}_1 , which are sampled with each set of 18-bit data words. Asserting the appropriate Byte Write Select input during the data portion of a write will allow the data being presented to be latched and written into the device. Deasserting the Byte Write Select input during the data portion of a write will allow the data stored in the device for that byte

to remain unaltered. This feature can be used to simplify Read/Modify/Write operations to a Byte Write operation.

Single Clock Mode

The CY7C1313V18 can be used with a single clock that controls both the input and output registers. In this mode the device will recognize only a single pair of input clocks (K and \overline{K}) that control both the input and output registers. This operation is identical to the operation if the device had zero skew between the $\overline{K/K}$ and C/C clocks. All timing parameters remain the same in this mode. To use this mode of operation, the user must tie C and \overline{C} HIGH at power on. This function is a strap option and not alterable during device operation.

Concurrent Transactions

The Read and Write ports on the CY7C1313V18 operate completely independently of one another. Since each port latches the address inputs on different clock edges, the user can Read or Write to any location, regardless of the transaction on the other port. If the ports access the same location when a read follows a write in successive clock cycles, the SRAM will deliver the most recent information associated with the specified address location. This includes forwarding data from a Write cycle that was initiated on the previous K clock rise.

Read accesses and Write access must be scheduled such that one transaction is initiated on any clock cycle. If both ports are selected on the same K clock rise, the arbitration depends on the previous state of the SRAM. If both ports were deselected, the Read port will take priority. If a Read was initiated on the previous cycle, the Write port will assume priority (since Read operations can not be initiated on consecutive cycles). If a Write was initiated on the previous cycle, the Read port will assume priority (since Write operations can not be initiated on

consecutive cycles). Therefore, asserting both port selects active from a deselected state will result in alternating Read/Write operations being initiated, with the first access being a Read.

Depth Expansion

The CY7C1313V18 has a Port Select input for each port. This allows for easy depth expansion. Both Port Selects are sampled on the rising edge of the Positive Input Clock only (K). Each port select input can deselect the specified port. Deselecting a port will not affect the other port. All pending transactions (Read and Write) will be completed prior to the device being deselected.

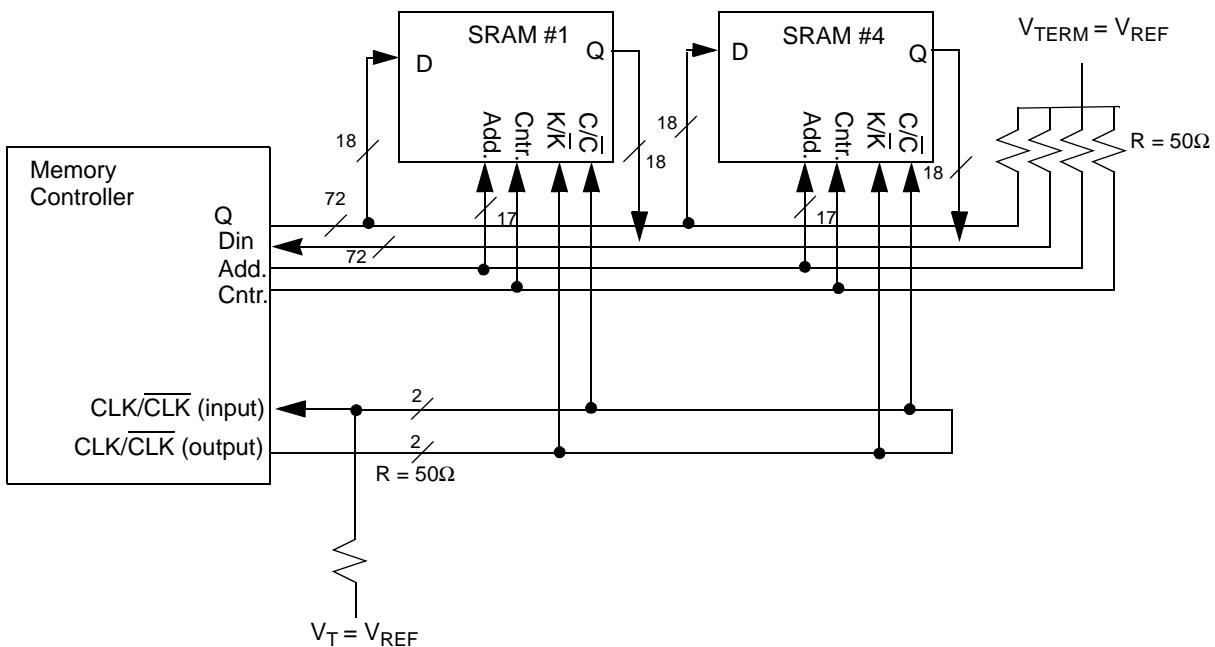

Programmable Impedance

An external resistor, R_Q , must be connected between the ZQ pin on the SRAM and V_{SS} to allow the SRAM to adjust its output driver impedance. The value of R_Q must be 5X the value of the intended line impedance driven by the SRAM, The allowable range of R_Q to guarantee impedance matching with a tolerance of $\pm 10\%$ is between 175Ω and 350Ω , with $V_{DDQ} = 1.5V$. The output impedance is adjusted every 1024 cycles to adjust for drifts in supply voltage and temperature.

Echo Clocks

Echo clocks are provided on the QDR-II to simplify data capture on high speed systems. Two echo clocks are generated by the QDR-II. CQ is referenced with respect to C and \overline{CQ} is referenced with respect to \overline{C} . These are free running clocks and are synchronized to the output clock of the QDR-II. In the single clock mode, CQ is generated with respect to K and \overline{CQ} is generated with respect to \overline{K} . The timings for the echo clocks are shown in the AC timing table.

Application Example^[2]

Note:

- The above application shows four CY7C1313V18s being used. This holds true for CY7C1311V18 and CY7C1315V18 as well.

Truth Table [3, 4, 5, 6, 7, 8]

Operation	K	RPS	WPS	DQ	DQ	DQ	DQ
Write Cycle: Load address on the rising edge of K; input write data on two consecutive K and \bar{K} rising edges.	L-H	H ^[9]	L ^[10]	D(A + 00) at K(t + 1) ↑	D(A + 01) at $\bar{K}(t + 1)$ ↑	D(A + 10) at K(t + 2) ↑	D(A + 11) at $\bar{K}(t + 2)$ ↑

H	H	-	L-H	No data is written into the devices during this portion of a write operation.

Notes:

- X = "Don't Care," H = Logic HIGH, L = Logic LOW, ↑ represents rising edge.
- Device will power-up deselected and the outputs in a three-state condition.
- "A" represents address location latched by the devices when transaction was initiated. A + 00, A + 01, A + 10, and A + 11 represents the address sequence in the burst.
- "t" represents the cycle at which a read/write operation is started. t + 1, t + 2, and t + 3 are the first, second and third clock cycles respectively succeeding the "t" clock cycle.
- Data inputs are registered at K and \bar{K} rising edges. Data outputs are delivered on C and \bar{C} rising edges, except when in single clock mode.
- It is recommended that K = \bar{K} and C = \bar{C} = HIGH when clock is stopped. This is not essential, but permits most rapid restart by overcoming transmission line charging symmetrically.
- If this signal was LOW to initiate the previous cycle, this signal becomes a "Don't Care" for this operation.
- This signal was HIGH on previous K clock rise. Initiating consecutive Read or Write operations on consecutive K clock rises is not permitted. The device will ignore the second Read or Write request.
- Assumes a Write cycle was initiated per the Write Port Cycle Description Truth Table. BWS₀, BWS₁ in the case of CY7C1311V18 and CY7C1313V18 and also BWS₂, BWS₃ in the case of CY7C1315V18 can be altered on different portions of a write cycle, as long as the set-up and hold requirements are achieved.

IEEE 1149.1 Serial Boundary Scan (JTAG)

The QDR-II incorporates a serial boundary scan test access port (TAP) in the FBGA package. This port operates in accordance with IEEE Standard 1149.1-1900, but does not have the set of functions required for full 1149.1 compliance. These functions from the IEEE specification are excluded because their inclusion places an added delay in the critical speed path of the SRAM. Note that the TAP controller functions in a manner that does not conflict with the operation of other devices using 1149.1 fully compliant TAPs. The TAP operates using JEDEC standard 1.8V I/O logic levels.

Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW (V_{SS}) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to V_{DD} through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state which will not interfere with the operation of the device.

Test Access Port—Test Clock

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

Test Mode Select

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this pin unconnected if the TAP is not used. The pin is pulled up internally, resulting in a logic HIGH level.

Test Data-in (TDI)

The TDI pin is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. For information on loading the instruction register, see the TAP Controller State Diagram. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) on any register.

Test Data-out (TDO)

The TDO output pin is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine (see Instruction codes). The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register.

Performing a TAP Reset

A Reset is performed by forcing TMS HIGH (V_{DD}) for five rising edges of TCK. This RESET does not affect the operation of the SRAM and may be performed while the SRAM is operating. At power-up, the TAP is reset internally to ensure that TDO comes up in a high-Z state.

TAP Registers

Registers are connected between the TDI and TDO pins and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through the instruction registers. Data is serially loaded into the TDI pin

on the rising edge of TCK. Data is output on the TDO pin on the falling edge of TCK.

Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO pins as shown in TAP Controller Block Diagram. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture IR state, the two least significant bits are loaded with a binary "01" pattern to allow for fault isolation of the board level serial test path.

Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between TDI and TDO pins. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW (V_{SS}) when the BYPASS instruction is executed.

Boundary Scan Register

The boundary scan register is connected to all the input and output pins on the SRAM. Several no connect (NC) pins are also included in the scan register to reserve pins for higher density devices.

The boundary scan register is loaded with the contents of the RAM Input and Output ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO pins when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE Z instructions can be used to capture the contents of the Input and Output ring.

The Boundary Scan Order tables show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

TAP Instruction Set

Eight different instructions are possible with the three-bit instruction register. All combinations are listed in the Instruction Code table. Three of these instructions are listed as RESERVED and should not be used. The other five instructions are described in detail below.

The TAP controller used in this SRAM is not fully compliant to the 1149.1 convention because some of the mandatory 1149.1 instructions are not fully implemented. The TAP controller cannot be used to load address, data or control signals into the SRAM and cannot preload the Input or Output buffers. The

SRAM does not implement the 1149.1 commands EXTEST or INTEST or the PRELOAD portion of SAMPLE/PRELOAD; rather it performs a capture of the Input and Output ring when these instructions are executed.

Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO pins. To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

EXTEST

EXTEST is a mandatory 1149.1 instruction which is to be executed whenever the instruction register is loaded with all 0s. EXTEST is not implemented in the TAP controller, and therefore this device is not compliant to the 1149.1 standard.

The TAP controller does not recognize an all-0 instruction. When an EXTEST instruction is loaded into the instruction register, the SRAM responds as if a SAMPLE/PRELOAD instruction has been loaded.

IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO pins and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state. The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO pins when the TAP controller is in a Shift-DR state.

SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1 mandatory instruction. The PRELOAD portion of this instruction is not implemented, so the TAP controller is not fully 1149.1 compliant.

When the SAMPLE/PRELOAD instruction is loaded into the instruction register and the TAP controller is in the Capture-DR

state, a snapshot of data on the input and output pins is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 10 MHz, while the SRAM clock operates more than an order of magnitude faster. Because there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.

To guarantee that the boundary scan register will capture the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller's capture setup plus hold times (t_{CS} and t_{CH}). The SRAM clock inputs might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the K, K, C, and \bar{C} captured in the boundary scan register.

Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.

Note that since the PRELOAD part of the command is not implemented, putting the TAP into the Update to the Update-DR state while performing a SAMPLE/PRELOAD instruction will have the same effect as the Pause-DR command.

Bypass

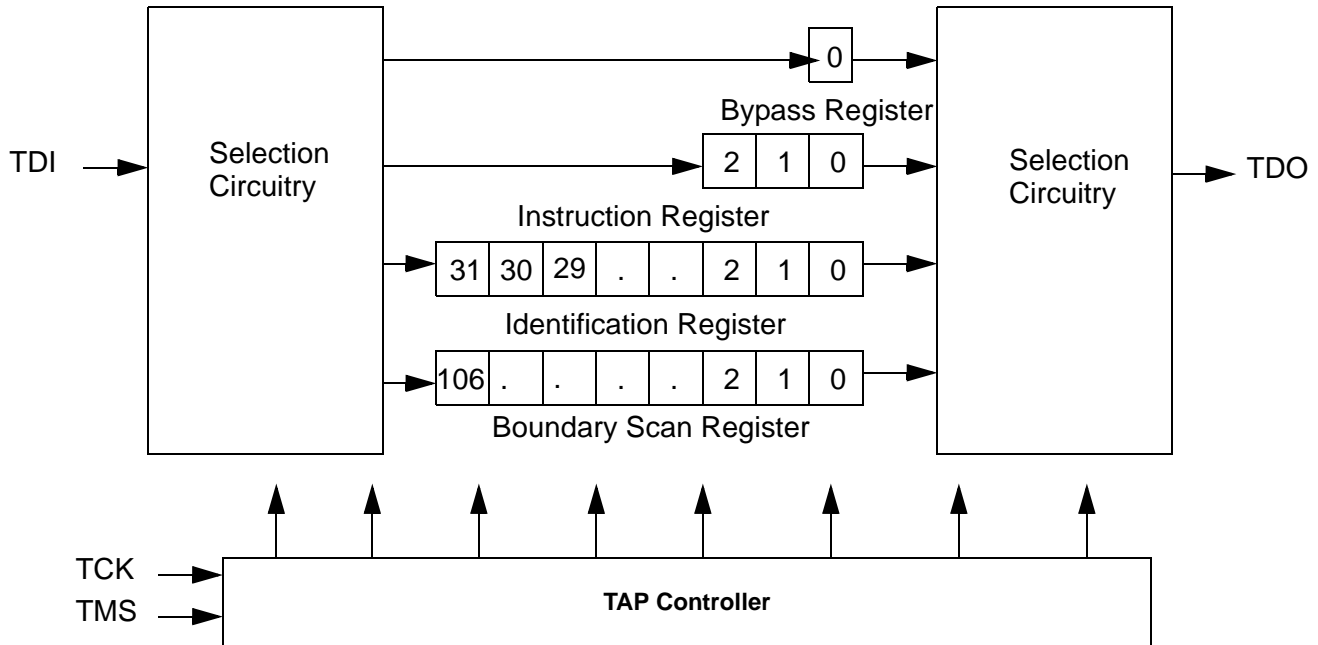

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO pins. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

Reserved

These instructions are not implemented but are reserved for future use. Do not use these instructions.

TAP Controller State Diagram^[24]

Note:
24. The 0/1 next to each state represents the value at TMS at the rising edge of TCK.

Instruction Codes

Instruction	Code	Description
EXTEST	000	Captures the Input/Output ring contents. Places the boundary scan register between the TDI and TDO. This instruction is not 1149.1 compliant. The EXTEST command implemented by these devices will NOT place the output buffers into a high-Z condition. If the output buffers need to be in high-Z condition, this can be accomplished by deselecting the Read port.
IDCODE	001	Loads the ID register with the vendor ID code and places the register between TDI and TDO. This operation does not affect SRAM operation.
SAMPLE Z	010	Captures the Input/Output contents. Places the boundary scan register between TDI and TDO. The SAMPLE Z command implemented by these devices will place the output buffers into a high-Z condition.
RESERVED	011	Do Not Use: This instruction is reserved for future use.
SAMPLE/PRELOAD	100	Captures the Input/Output ring contents. Places the boundary scan register between TDI and TDO. Does not affect the SRAM operation. This instruction does not implement 1149.1 preload function and is therefore not 1149.1 compliant.
RESERVED	101	Do Not Use: This instruction is reserved for future use.
RESERVED	110	Do Not Use: This instruction is reserved for future use.
BYPASS	111	Places the bypass register between TDI and TDO. This operation does not affect SRAM operation.
