TIMING DIAGRAMS

TIMING WAVEFORM OF READ CYCLE(1)(Address Controlled)

(CS=OE=V_{IL}, WE=V_{IH})

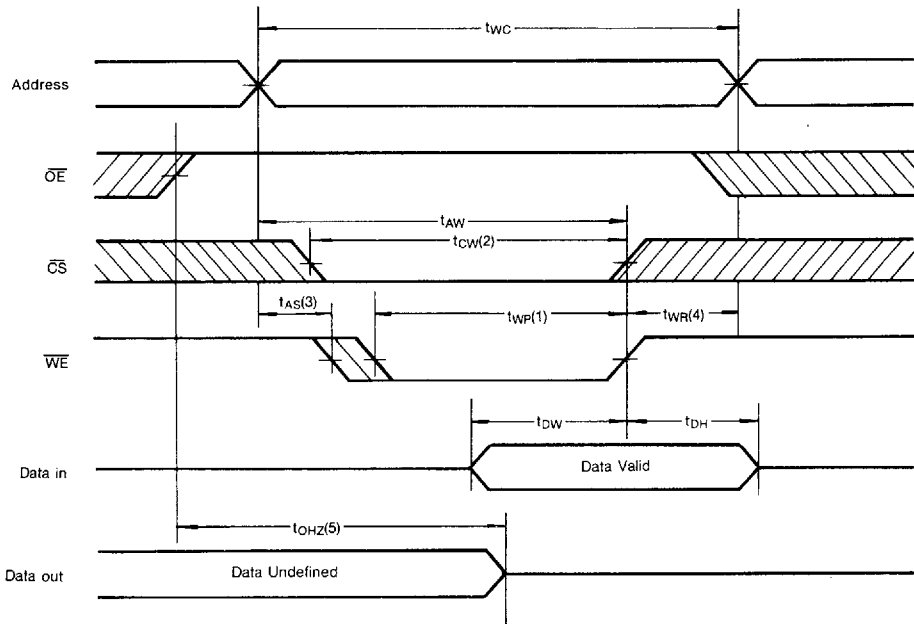

TIMING WAVEFORM OF READ CYCLE (2) ($\overline{WE} = V_{IH}$)

Notes (READ CYCLE)

1. t_{HZ} and t_{OHZ} are defined as the time at which the outputs achieve the open circuit condition and are not referenced to V_{OH} or V_{OL} levels.
2. At any given temperature and voltage condition, t_{HZ} (max.) is less than t_{LZ} (min.) both for a given device and from device to device.

TIMING WAVEFORM OF WRITE CYCLE (1) ($\overline{OE} = \text{Clock}$)

TIMING WAVEFORM OF WRITE CYCLE (2) (\overline{OE} = Low Fixed)

Notes (WRITE CYCLE)

1. A write occurs during the overlap of a low \overline{CS} and a low \overline{WE} . A write begins at the latest transition among \overline{CS} going low and \overline{WE} going low: A write ends at the earliest transition among \overline{CS} going high and \overline{WE} going high. t_{WP} is measured from the beginning of write to the end of write.
2. t_{CW} is measured from the later of \overline{CS} going low to end of write.
3. t_{AS} is measured from the address valid to the beginning of write.
4. t_{WR} is measured from the end of write to the address change. t_{WR} applied in case a write ends as \overline{CS} , or \overline{WE} going high.
5. During this period, the I/O pins are in the outputs Low-Z state. Inputs of opposite phase of the output must not be applied because bus contention can occur.
6. If \overline{CS} goes low simultaneously with \overline{WE} going low or after \overline{WE} going low, the outputs remain high impedance state.
7. D_{OUT} is the some phase of latest written data in this write cycle.
8. D_{OUT} is the read data of the new address.
