

DC Operating Conditions**Absolute Maximum Ratings** ⁽¹⁾

	<i>max</i>	<i>unit</i>
Voltage on any pin w.r.t. Gnd ⁽²⁾ (except A9)	-2.0 to +7	V
Supply Voltage ⁽²⁾	-2.0 to +7	V
Voltage on A ₉ w.r.t. Gnd	-2.0 to +14	V
Storage Temperature	-55 to +150	°C

Notes : (1) Stresses above those listed may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational sections of this specification is not implied.

(2) Minimum DC voltage on any input or I/O pin is -0.5V. Maximum DC voltage on output and I/O pins is $V_{CC}+0.5V$. During transitions voltage may overshoot by $\pm 2V$ for upto 20ns

Recommended Operating Conditions

<i>Parameter</i>	<i>Symbol</i>	<i>min</i>	<i>typ</i>	<i>max</i>	<i>unit</i>

AC Waveforms for Read Operation

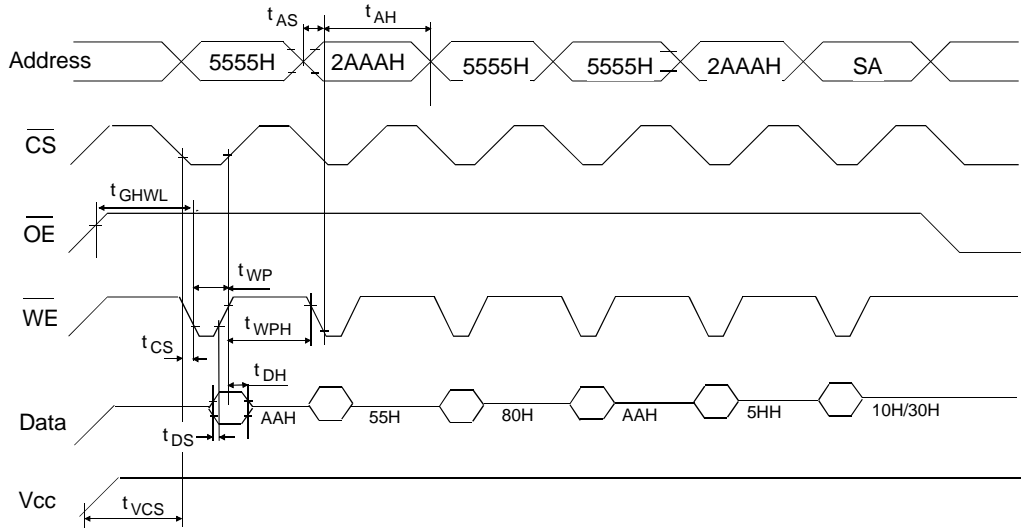

AC Programming Waveforms

Notes:

1. PA is address of the memory location to be programmed.
2. PD is data to be programmed at byte address.
3. \overline{D}_7 is the output of the complement of the data written to the device.
4. DOUT is the output of the data written to the device.
5. Figure indicates last two bus cycles of four bus cycle sequence.

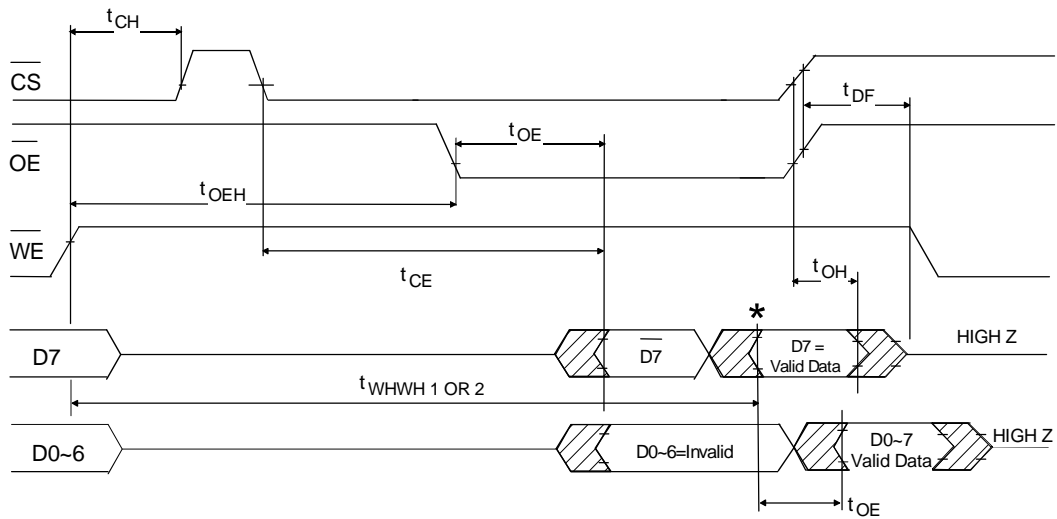

AC Chip / Sector Erase Waveforms

NOTES:

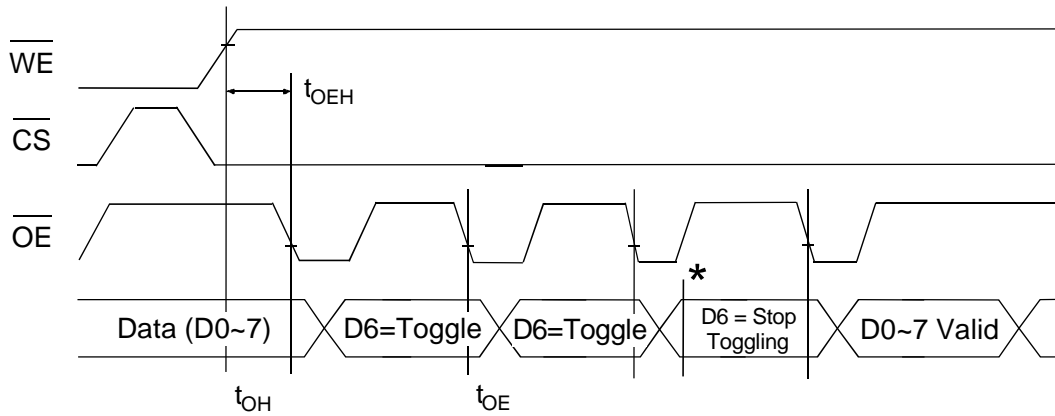

- 1. SA is the address for Sector Erase. Addresses = don't care for Chip Erase.

AC Waveforms for Data Polling During Embedded Algorithm Operations

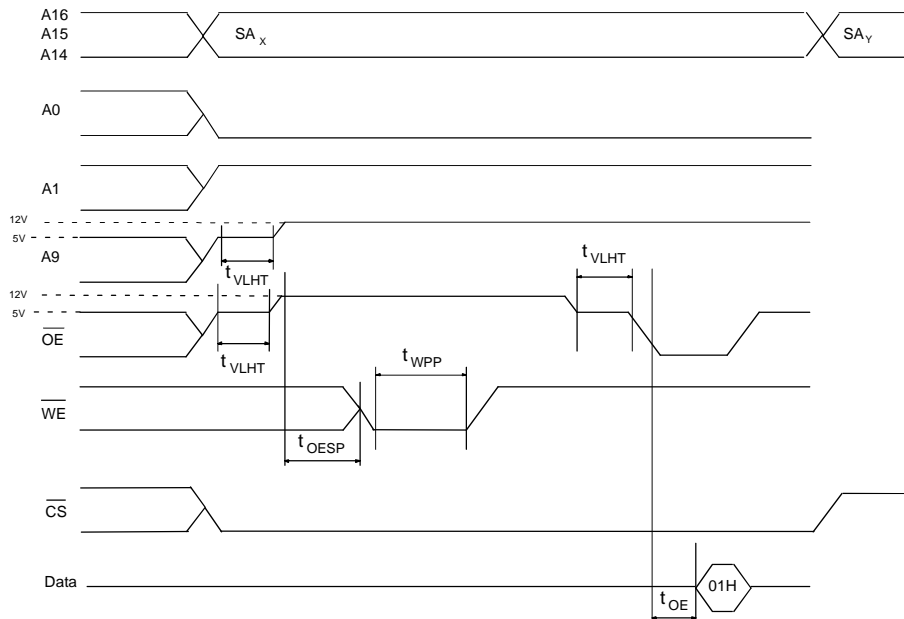

* D7 = Valid data (The device has completed the Embedded Operation).

AC Waveforms for Toggle Bit During Embedded Algorithm Operations

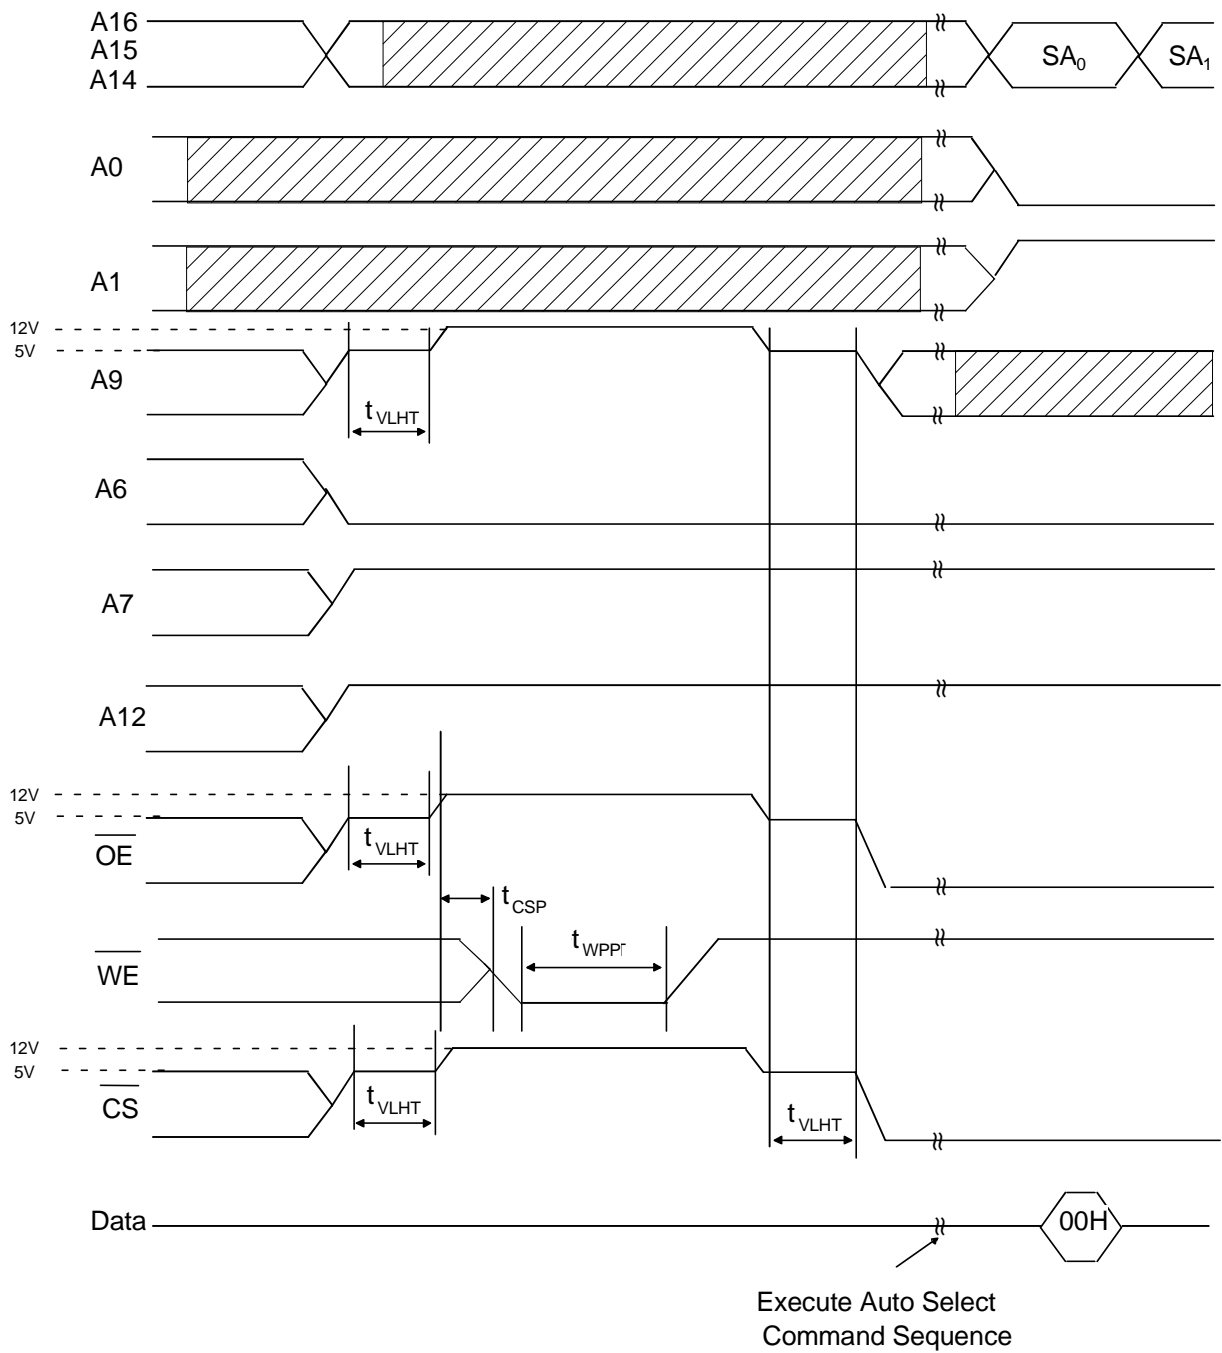

D₆ stops toggling (The device has completed the Embedded operation).

AC Waveforms For Sector Protection

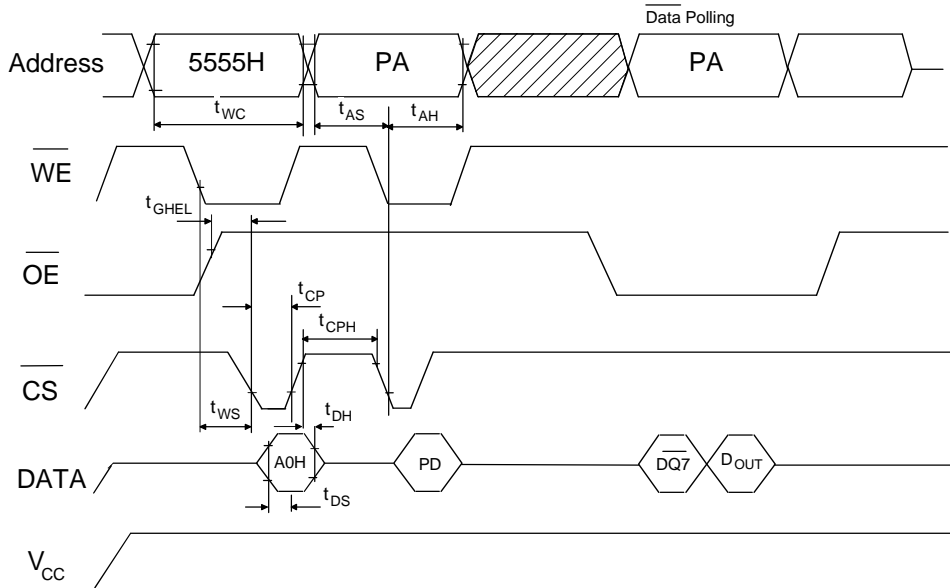

SAX = sector Addr for initial sector
 SAY = sector Addr for next sector

AC Waveforms for Sector Unprotect

A.C Waveforms - Alternate \overline{CS} controlled Program operation timings

NOTES:

1. PA is address of memory location to be programmed.
2. PD is data to be programmed at byte address.
3. $\overline{D_7}$ is the output of the complement of the data written to the device.
4. D_{OUT} is the output of the data written to the device.
5. Figure indicates last two bus cycles of four bus cycle sequence.

Command Definitions

Device operations are selected by writing specific address and data sequences into the command register. The following table defines these register command sequences.

COMMAND SEQUENCE	Bus Write Cycle Req'd	First Bus Write Cycle		Second Bus Write Cycle		Third bus Write Cycle		Fourth bus Read/Write Cycle		Fifth Bus Write Cycle		Sixth Bus Write Cycle	
		Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data	Addr	Data
Read/Reset	4	5555H	AAH	2AAAH	55H	5555H	F0H	RA	RD				
Autoselect	4	5555H	AAH	2AAAH	55H	5555H	90H	00H/01H	01H/20H				
Byte Program	4	5555H	AAH	2AAAH	55H	5555H	A0H	PA	PD				
Chip erase	6	5555H	AAH	2AAAH	55H	5555H	80H	5555H	AAH	2AAAH	55H	5555H	10H
Sector erase	6	5555H	AAH	2AAAH	55H	5555H	80H	5555H	AAH	2AAAH	55H	SA	30H

NOTES:

- Address bit $A_{15}=X=$ Don't care. Write Sequences may be initiated with A_{15} in either state.
- Address bit $A_{16}=X=$ Don't care for all address commands except for Program Address (PA) and Sector Address (SA).
- RA=Address of the memory location to be read.
PA=Address of memory location to be programmed. Addresses are latched on the falling edge of the \overline{WE} pulse.
SA=Address of the sector to be erased. The combination of A_{16} , A_{15} and A_{14} will uniquely select any sector.
- RD=Data read from location RA during read operation.
PD=Data to be programmed at location PA. Data is latched on the falling edge of \overline{WE}

Read/Reset Command

The read or reset operation is initiated by writing the read/reset command sequence into the command register. Microprocessor read cycles retrieve array data from the memory. The device remains enabled for reads until the command register contents are altered.

The device will automatically power-up in the read/reset state. In this case, a command sequence is not required to read data. Standard microprocessor read cycles will retrieve array data. This default value ensures that no spurious alteration of memory content occurs during the power transition. Refer to the AC Read Characteristics and Waveforms for specific timing parameters.

Read Mode

The MFM8126 has two control functions which must be satisfied in order to obtain data at the outputs
 \overline{CS} is the power control and should be used for device selection
 \overline{OE} is the output control and should be used to gate data to the output pins if the device is selected.

Standby Mode

Two standby modes are available :

CMOS standby : \overline{CS} held at $V_{CC} \pm 0.5V$

TTL standby : \overline{CS} held at V_{IH}

In the standby mode the outputs are in a high impedance state independent of the \overline{OE} input. If the device is deselected during erasure or programming the device will draw active current until the operation is completed.

Output Disable

With the \overline{OE} input at a logic high level (V_{IH}), output from the device is disabled. This will cause the output pins to be in a high impedance state.

Autoselect

The autoselect mode allows the reading out of a binary code from the device and will identify the device manufacturer and type. This mode is intended for use by programming equipment. This mode is functional over the full military temperature range. The autoselect codes are as follows :

	A ₁₆	A ₁₅	A ₁₄	A ₁	A ₀	CODE (HEX)	D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀
DIE Manufacturer code	X	X	X	V _{IL}	V _{IL}	01H	0	0	0	0	0	0	0	1
DIE device code	X	X	X	V _{IL}	V _{IH}	20H	0	0	1	0	0	0	0	0
Sector protection	Sector Address			V _{IH}	V _{IL}	01H*	0	0	0	0	0	0	0	1

* Outputs 01H at protected sector address. Outputs 00H at unprotected sector address.

To activate this mode the programming equipment must force V_{ID} (11.5 to 12.5V) on address A₉. Two identifier bytes may then be sequenced from the device outputs by toggling A₀ from V_{IL} to V_{IH}. All addresses are don't care apart from A₁ & A₀. All identifiers for manufacturer and device will exhibit odd parity with D₇ defined as the parity bit.

The manufacturer and device codes may also be read via the command register, for instances when the MFM8126 is erased or programmed in a system without access to high voltage on A₉. All identifiers for manufacturers and device will exhibit odd parity with the MSB(D₇) defined as the parity bit. In order to read the proper device codes when executing the Autoselect, A₁ must be V_{IL}.

Write

Device erasure and programming are accomplished via the command register. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device. The register is a latch used to store the commands along with the address and data information required to execute the command. The command register is written by bringing \overline{WE} to V_{IL} while \overline{CS} is at V_{IL} and \overline{OE} is at V_{IH}. Addresses are latched on the falling edge of \overline{WE} while data is latched on the rising edge.

Sector Protection

The MFM8126 features hardware sector protection. This feature will disable both program and erase operations in any number of sectors (0 through 7). The sector protect feature is enabled using programming equipment at the users site. The device is shipped with all sectors unprotected.

To activate this mode, the programming equipment must force V_{ID} on address pin A_9 and control pin \overline{OE} . The sector addresses (A_{16} , A_{15} and A_{14}) should be set to the sector to be protected. Programming of the protection circuitry begins on the falling edge of the \overline{WE} pulse and is terminated with the rising edge of the same. Sector addresses must be held constant during the \overline{WE} pulse. (See Sector Address Table). To verify programming of the protection equipment circuitry, the programming equipment must force V_{ID} on address pin A_9 with \overline{CS} and \overline{OE} at V_{IL} and \overline{WE} at V_{IH} . Reading the device at a particular sector address (A_{16} , A_{15} and A_{14}) will produce 01H at data outputs (D_0 - D_7) for a protected sector. Otherwise the device will read 00H for unprotected sector. In this mode, the lower order addresses, except for A_0 and A_1 , are don't care. Address location 02H is reserved to verify sector protection of the device. Address pin A_1 must be held at V_{IH} and A_0 at V_{IL} . Address location 00H and 01H are reserved for autoselect codes. If a verify of the sector protection circuitry were done at these addresses, the device would output the manufacturer and device codes respectively.

It is also possible to determine if a sector is protected in the system by writing the autoselect command. Performing a read operation at particular sector addresses (A_{16} , A_{15} and A_{14}) and with $A_1=V_{IH}$ and $A_0=V_{IL}$ (other addresses are a don't care) will produce 01H data if those sectors are protected. Otherwise the device will read 00H for an unprotected sector. (See Sector Protect/Unprotect Algorithms for more details.)

Sector Adresses Table.

	A_{16}	A_{15}	A_{14}	Address Range
SA0	0	0	0	0000H-3FFFFH
SA1	0	0	1	04000H-07FFFFH
SA2	0	1	0	08000H-0BFFFFH
SA3	0	1	1	0C000H-0FFFFH
SA4	1	0	0	10000H-13FFFFH
SA5	1	0	1	14000H-17FFFFH
SA6	1	1	0	18000H-1BFFFFH
SA7	1	1	1	1C000H-1FFFFH

Auto Select Command

Flash memories are intended for use in applications where the local CPU alters memory contents. As such, manufacture and device codes must be accessible while the device resides in the target systems. PROM programmers typically access the signature codes by raising A_9 to a high voltage. However, multiplexing high voltage onto the address lines is not generally a desired system design practice.

The device contains an autoselect operation to supplement traditional PROM programming methodology. The operation is initiated by writing the autoselect command sequence into the command register. Following the command write, a read cycle from address XXX0H retrieves the manufacture code of 01H. A read cycle from address XXX1H returns the device code 20H. A read cycle from address XXX2H returns information as to which sectors are protected. All manufacturer and device codes will exhibit odd parity with the MSB (D_7) defined as the parity bit.

To terminate the operation, it is necessary to write the read/reset command sequence into the register.

Byte Programming

The device is programmed on a byte-by-byte basis. Programming is a four bus cycle operation. There are two "unlock" write cycle. These are followed by the program set-up command and data write cycles. The addresses are latched on the falling edge of \overline{CS} or \overline{WE} (whichever last), the data is latched on the rising edge of \overline{CS} or \overline{WE} (whichever first), and then programming begins. Upon executing the Embedded Program Algorithm Command sequence the system is not required to provide further controls or timings. The device will automatically provide adequate internally generated program pulses and verify the programmed cell margin. The automatic programming operation is completed when the data on D_7 is equivalent to data written to this bit (see write Operations Status) at which time the device returns to read mode and addresses are no longer latched. Data Polling must be performed at the memory location which is being programmed.

Programming is allowed in any address sequence and across sector boundaries. Beware that data "0" cannot be programmed back to a "1". Attempting to do so will hang up the device, or result in an apparent success according to the data polling algorithm. However, a read from Read/Reset Mode will show data is still "0". **Only an erase operation can convert "0"s to "1"s.**

Chip Erase

Chip erase is a six bus cycle operation. There are two "unlock" write cycles. These are followed by writing the "set-up" command. Two more "unlock" write cycles are then followed by the chip erase command.

Chip erase doesn't require the user to program the device prior to erase. Upon executing the Embedded Erase Algorithm command sequence the device automatically will program and verify the entire memory for an all zero data pattern prior to electrical erase. The systems is not required to provide any controls or timings during these operations.

The automatic erase begins on the rising edge of the last \overline{WE} pulse in the command sequence and terminates when the data on D_7 is "1" (See Written Operation Section) at which time the device returns to read the mode.

Sector Erase

Sector erase is a six bus cycle operation. There are two "unlock" write cycles. These are followed by writing the "Set-up" command. Two more "unlock" write cycles are then followed by the sector erase command. The sector address (any address location within the desired sector) is latched on the falling edge of \overline{WE} , while the command (data) is latched on the rising edge of \overline{WE} . A time-out of 80 μ s from the rising edge of the last sector erase command will initiate the sector erase command(s).

Multiple sectors may be erased concurrently by writing the six bus cycle operations as described above. This sequence is followed with writes of the sector erase command (30H) to addresses in other sectors required to be concurrently erased. The time between writes must be less than 80 μ s, otherwise that command will not be accepted. It is recommended that processor interrupts be disabled during this time to guarantee this condition.

The interrupts can be re-enabled after the last Sector Erase command(s). If another falling edge of \overline{WE} occurs within the 80 μ s time-out window, the timer is reset. (D_3 indicates if the timer window is still open). Loading the sector erase buffer may be done in any sequence and with any number of sectors (0 to 7). Any command other than Sector Erase during this period will reset the device to read mode, ignoring the previous.

Sector erase doesn't require the user to program the device prior to erase. The device automatically programs all memory locations in the sector(s) to be erased prior to electrical erase. When erasing a sector or sectors the remaining unselected sectors are not affected. The system is not required to provide any controls or timings during these operations.

The automatic sector erase begins after the 100 μ s time-out from the rising edge of the \overline{WE} pulse for the last sector erase command pulse and terminates when the data on D_7 is "1" (see Write Operation Status Section) at which time the device returns to read mode. Data polling must be performed at an address within any of the sectors being erased.

Write Operations Status

Hardware Sequence Flags

	STATUS	D_7	D_6	D_5	D_3	D_2-D_0
In Progress	Auto-Programming	$\overline{D_7}$	Toggle	0	0	Reserved for future use
	Programming in auto erase	0	Toggle	0	1	
	Erasing in Auto Erase	0	Toggle	0	1	
Exceeded Time limits	Auto-Programming	$\overline{D_7}$	Toggle	1	0	Reserved for future use
	Programming in auto erase	0	Toggle	1	1	
	Erasing in Auto-Erase	0	Toggle	1	1	

Data Polling - D_7

The MFM8126 features Data Polling as a method to indicate to the host system that the Embedded Algorithms are in progress or completed.

During the Embedded Programming Algorithm, an attempt to read the device will produce complement data of the data last written to D_7 . Upon completion of the Embedded Programming Algorithm an attempt to read the device will produce the true data last written to D_7 . Data Polling is valid after the rising edge of the fourth \overline{WE} pulse in the four write pulse sequence.

During the Embedded Erase Algorithm, D_7 will be "0" until the erase operation is completed. Upon completion data at D_7 is "1". For chip erase, the Data Polling is valid after the rising edge of the sixth \overline{WE} pulse in the six write pulse sequence. For sector erase, Data Polling is valid after the last rising edge of the sector erase \overline{WE} pulse.

The Data Polling feature is only active during the Embedded Programming Algorithm, Embedded Erase Algorithm, or sector erase time-out.

Toggle Bit - D₆

The MFM8126 also features the "toggle bit" as a method to indicate to the host system that the Embedded Algorithms are in progress or completed.

During an Embedded Program or Erase Algorithm cycle, successive attempts to read ($\overline{\text{OE}}$ Toggling) data from the device will result in D₆ toggling between one and zero. Once the Embedded Program or Erase Algorithm cycle is completed, D₆ will stop toggling and valid data will be read on successive attempts. During programming, the Toggle bit is valid after the rising edge of the fourth WE pulse in the four write pulse sequence. For chip erase, the Toggle bit is valid after the sixth WE pulse in the six write pulse sequence.

For sector erase, the Toggle bit is valid after the last rising edge of the sector erase WE pulse. The Toggle Bit is active during the sector time-out. Note: $\overline{\text{CS}}$ or $\overline{\text{OE}}$ toggling will toggle D₆.

Exceeding Time Limits - D₅

D₅ will indicate if the program or erase time has exceeded the specified limits. Under these conditions D₅ will produce "1", indicating the program or erase cycle was not successfully completed. Data Polling is the only operating function of the device under this condition. The $\overline{\text{CS}}$ circuit will partially power down the device under these conditions (to approximately 2mA). The OE and WE pins will control the output disable functions. To reset the device, write reset command sequence to the device. This allows the system to continue to use the other active sectors in the device.

If this failure condition occurs during the sector erase operation, it specifies that a particular sector is bad and it may not be reused. However, other sectors are still functional and may be used for additional program or erase operations. The device must be reset to use other sectors. Write the Reset command sequence to the device, and then execute the program or erase command sequence.

If this failure condition occurs during the chip erase operation, it specifies that the entire chip is bad or combination of sectors are bad.

If this failure condition occurs during the byte programming operation, it specifies that the entire sector containing that byte is bad and this sector may not be reused (other sectors are still functional and can be reused). The device must be reset to use other sectors.

The D₅ failure condition may also appear if a user tries to program a non blank location without erasing. In this case the system never reads valid data on the D₇ bit and D₆ never stops toggling. Once the device has exceeded timing limits, the D₅ bit will indicate a "1". Please note that this is not a device failure condition since the device was incorrectly used. The device must be reset to continue using the device.

Hardware Sequence Flag - D₄

If the device has exceeded the specified erase or program time and D₅ is "1", then D₄ will indicate at which step in the algorithm the device exceeded the limits. A "0" in D₄ indicates in programming, a "1" indicates an erase.

Sector Erase Timer - D₃

After the completion of the initial sector erase command sequence the sector erase time-out will begin. D₃ will remain low until the time-out is complete. Data Polling and Toggle Bit are valid after the initial sector erase command sequence.

If $\overline{\text{Data Polling}}$ or the Toggle Bit indicates the device has been written with a valid erase command, D_3 may be used to determine if the sector erase timer window is still open. If D_3 is high the internally controlled erase cycle has begun; attempts to write subsequent commands to the device will be ignored until the erase operation is completed as indicated by $\overline{\text{Data Polling}}$ or Toggle Bit. If D_3 is low, the device will accept additional sector erase commands. To insure the command has been accepted, the software should check the status of D_3 prior to and following each subsequent sector erase command. If D_3 were high on the second status check, the command may not have been accepted.

Data Protection

The MFM8126 is designed to offer protection against accidental erasure or programming caused by spurious system level signals that may exist during power transition. During power up the device automatically resets the internal state machine in the Read mode. Also, with its controls register architecture, alteration of the memory contents only occurs after successful completion of specific multi-bus cycle command sequences. The device also incorporates several features to prevent inadvertent write cycles resulting from V_{CC} power up and power down transitions or system noise.

Low V_{CC} Write Inhibit

To avoid initiation of a write cycle during V_{CC} power up and power down, a write cycle is locked out for V_{CC} less than 3.2V (typically 3.7V). If $V_{CC} < V_{LKO}$, the command register is disabled and all internal program/erase circuits are disabled. Under this condition the device will reset to read mode. Subsequent writes will be ignored until the V_{CC} level is greater than V_{LKO} . It is usually correct to prevent unintentional writes when V_{CC} is above 3.2V.

Write Pulse "Glitch" Protection

Noise pulses of less than 5ns (typical) on $\overline{\text{OE}}$, $\overline{\text{CS}}$, $\overline{\text{WE}}$ will not initiate a write cycle

Logical Inhibit

Writing is inhibited by holding any one of $\overline{\text{OE}}=V_{IL}$, $\overline{\text{CS}}=V_{IH}$ or $\overline{\text{WE}}=V_{IH}$. To initiate a write cycle $\overline{\text{CS}}$ and $\overline{\text{WE}}$ must be logical zero while $\overline{\text{OE}}$ is a logical one.

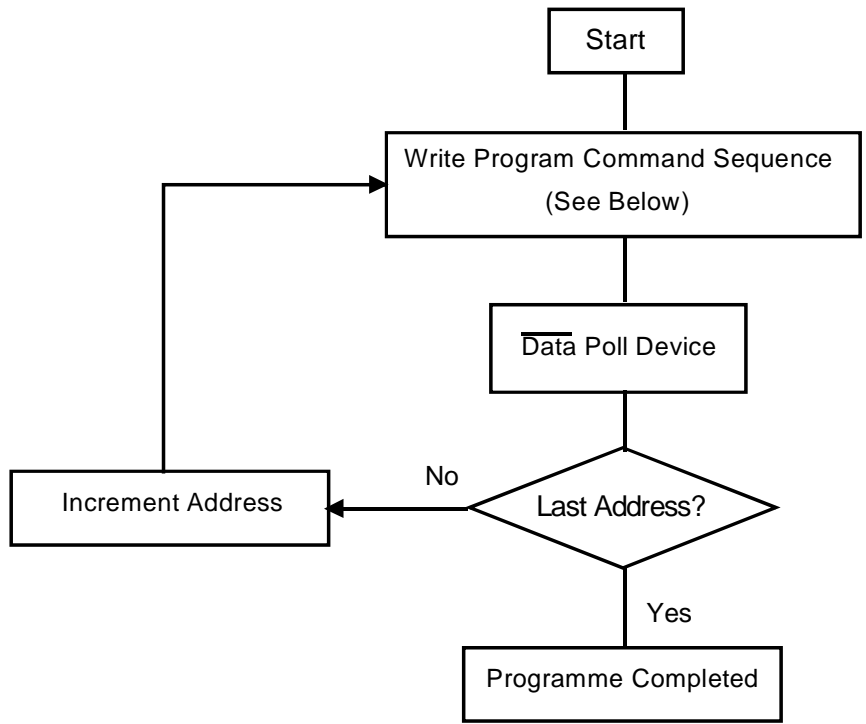

Power-Up Write Inhibit

Power-up of the device with $\overline{\text{WE}}=\overline{\text{CS}}=V_{IL}$ and $\overline{\text{OE}}=V_{IH}$ will not accept commands on the rising edge of $\overline{\text{WE}}$. The internal state machine is automatically reset to the read mode on power-up.

Sector Protect

Sectors of the MFM8126 may be hardware protected at the users factory. The protection circuitry will disable both program and erase functions for the protected sector(s). Requests to program or erase a protected sector will be ignored by the device.

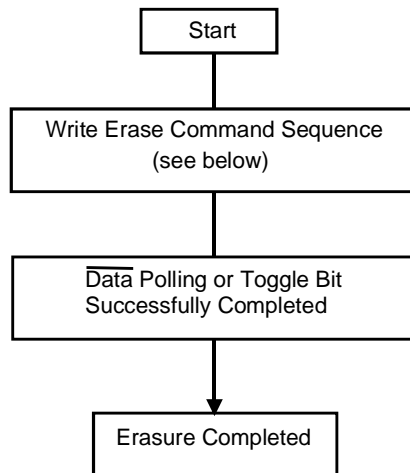

Embedded Programming Algorithm

Program Command Sequence (Address/Command)

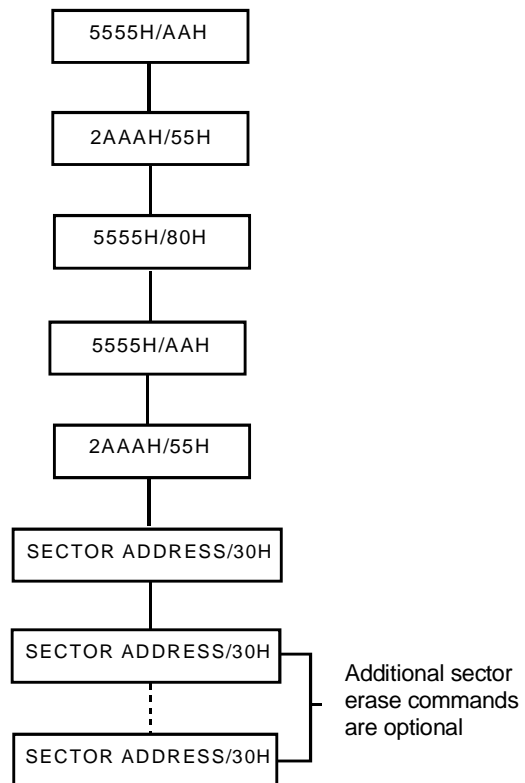

Embedded Erase Algorithm

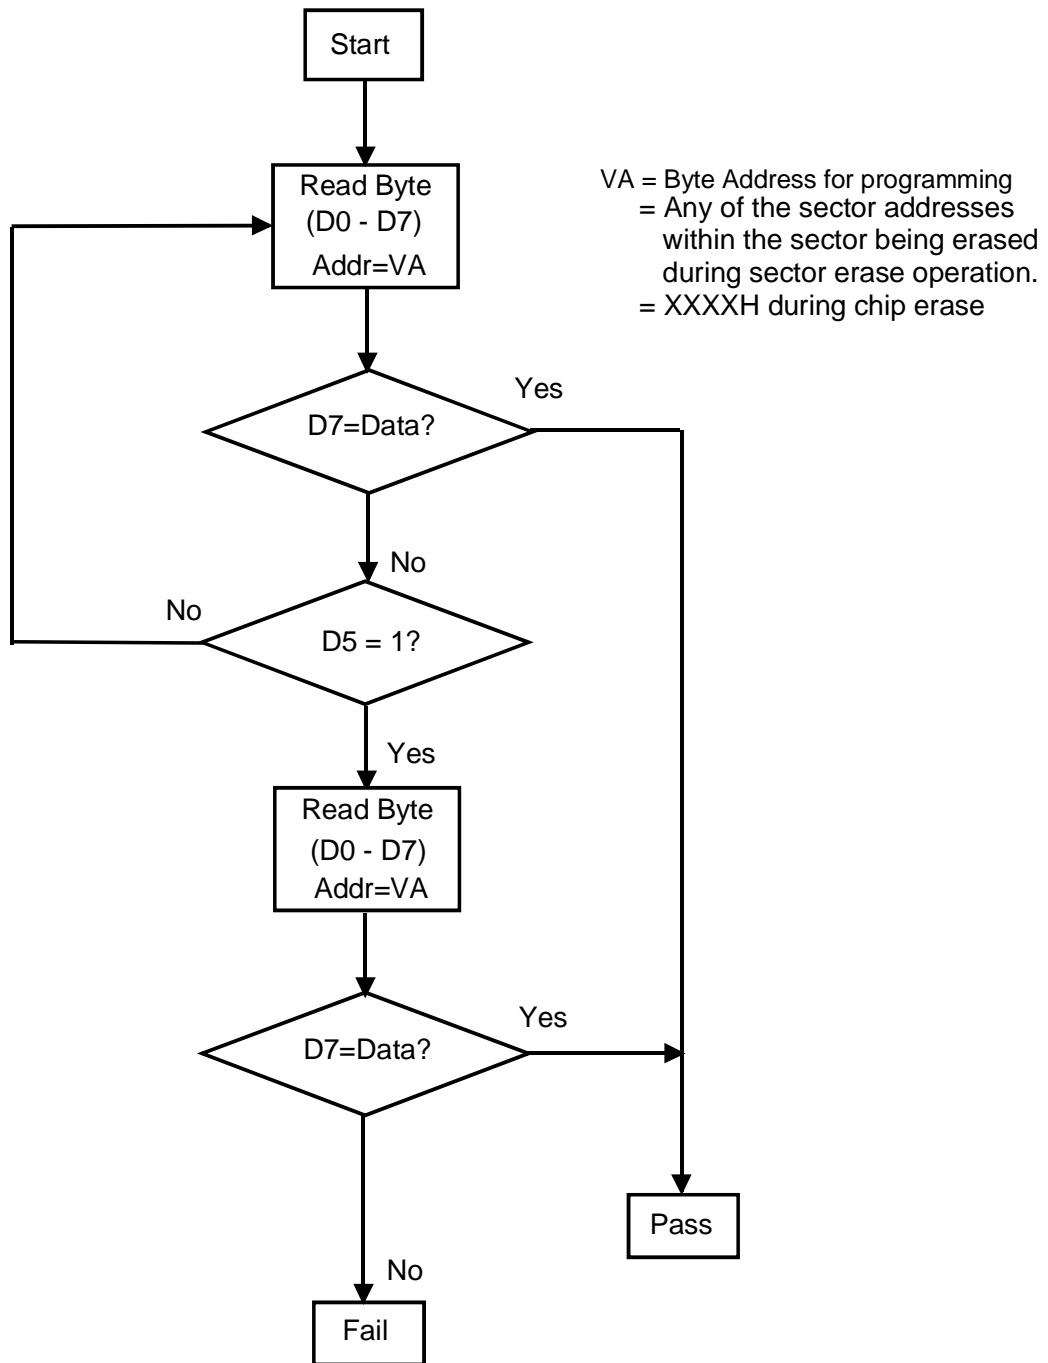

Chip Erase Command Sequence
(Address/Command):

Individual Sector/Multiple Sector
Erase Command Sequence
(Address/Command)

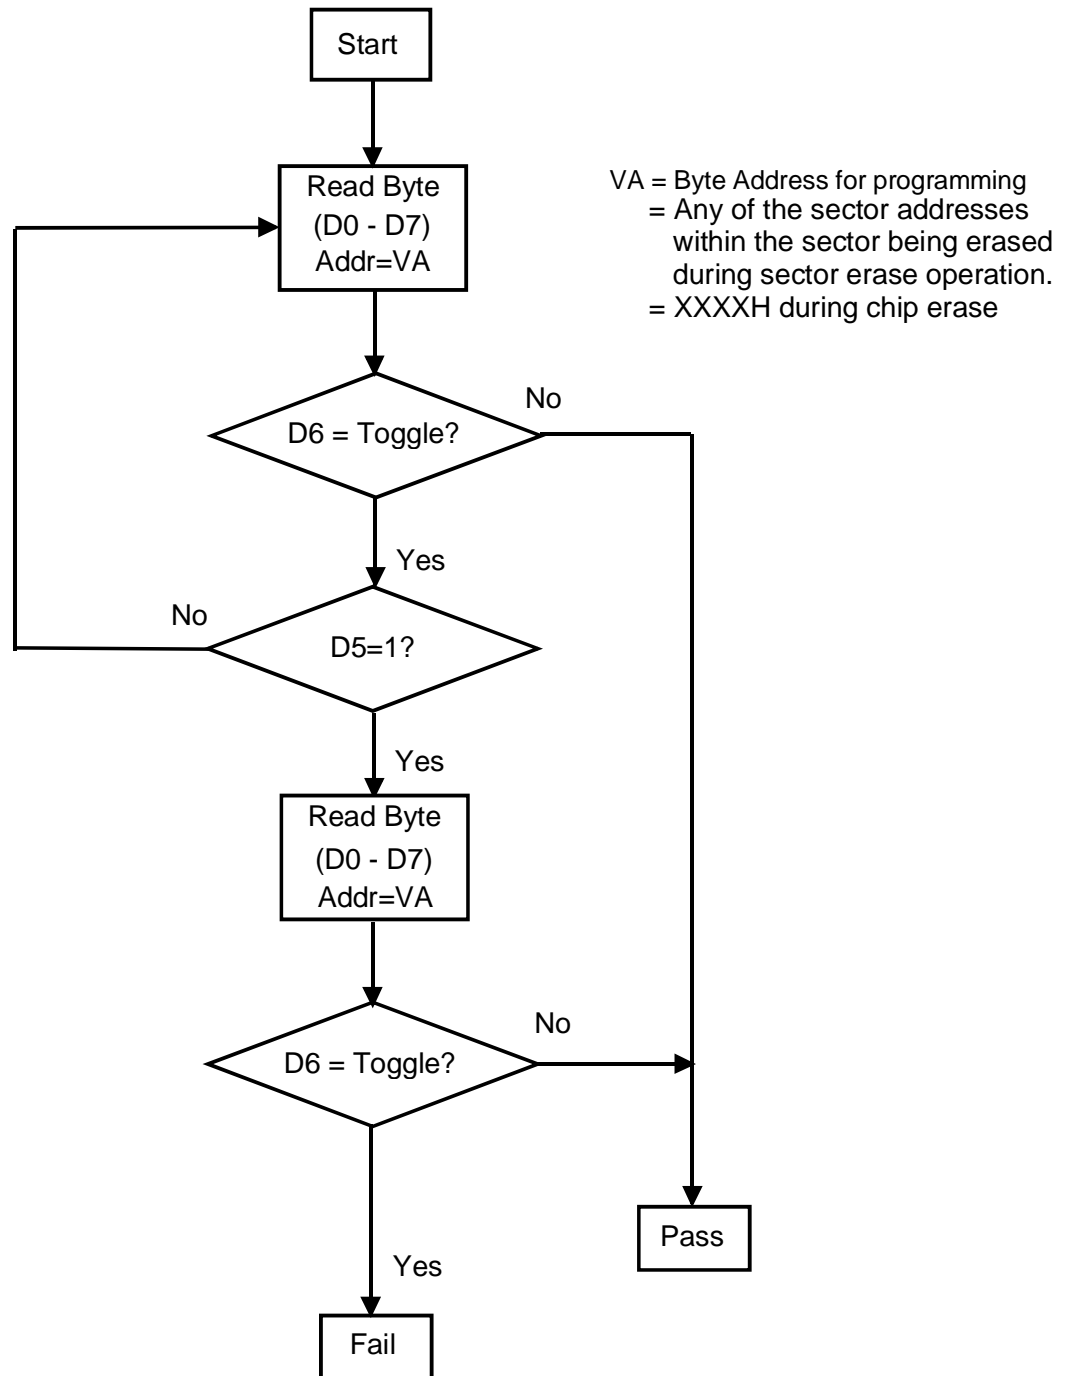

Data Polling Algorithm

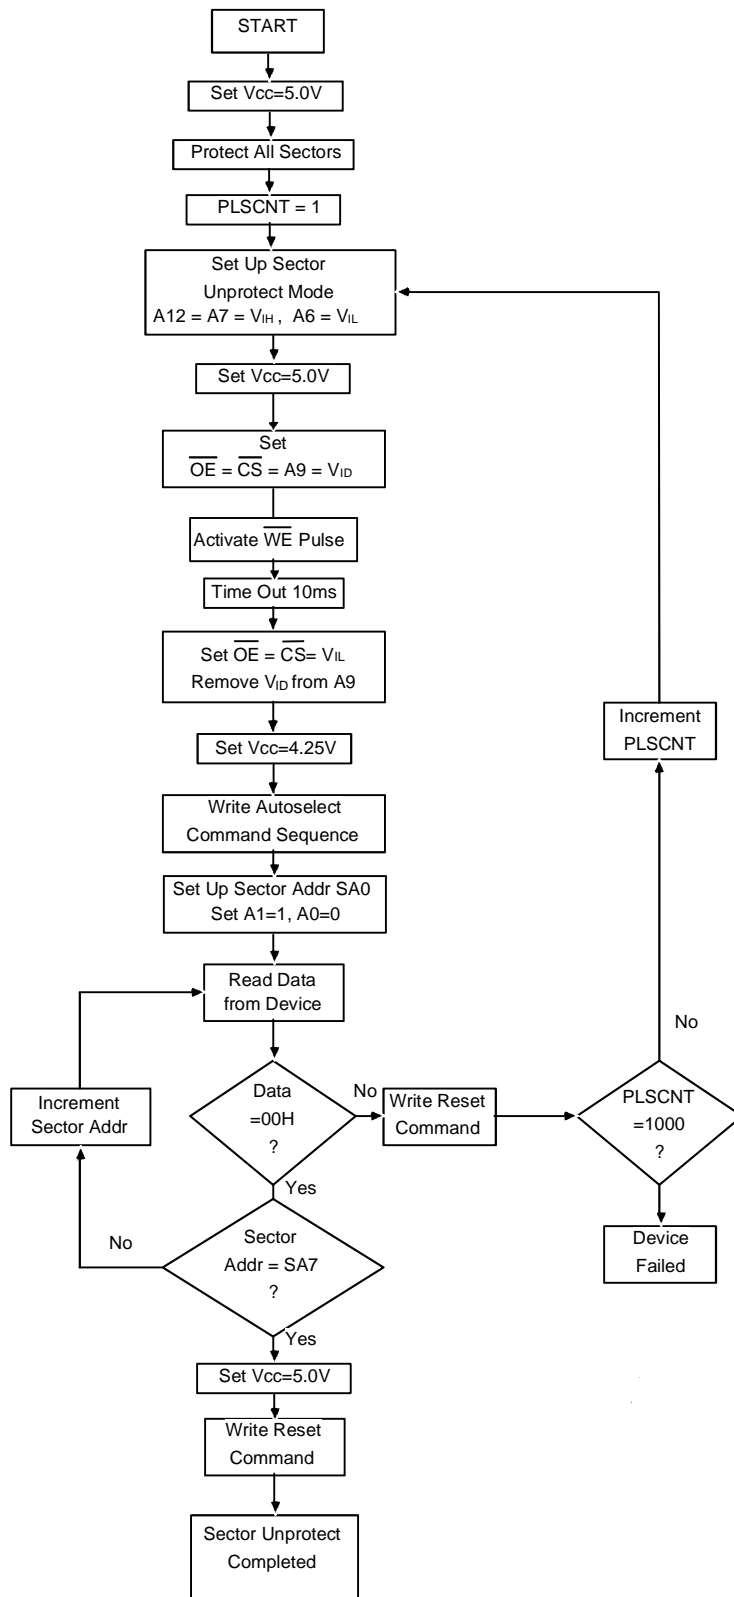

Note : D7 is rechecked even if D5 = "1" because D7 may change simultaneously with D5.

Toggle Bit Algorithm

Note : D6 is rechecked even if D5 = "1" because D6 may stop toggling at the same time as D5 changing to "1"

Sector Unprotect Algorithm

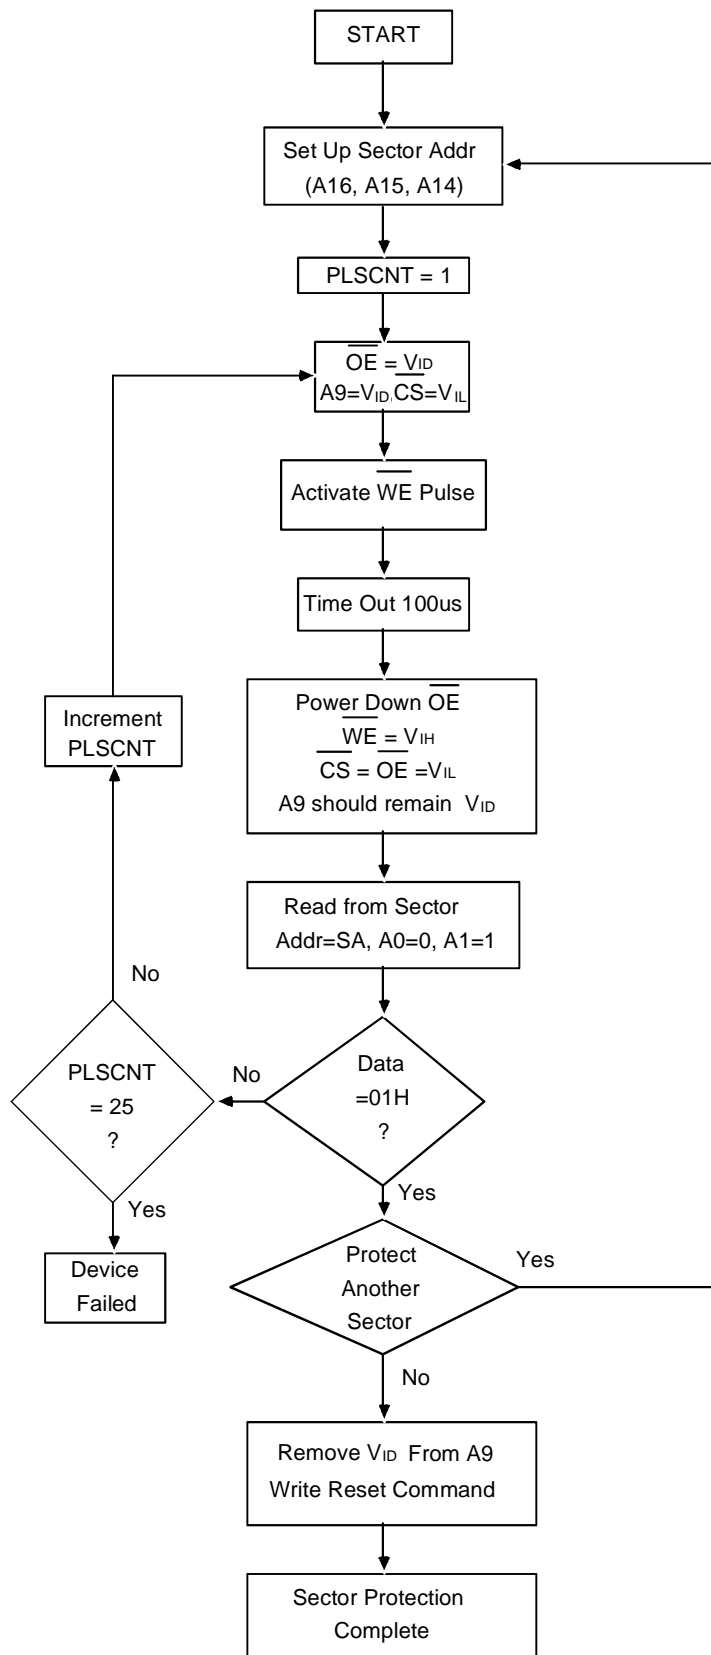

NOTES:

SA0 = Sector Addr for initial sector

SA7 = Sector Addr to last sector

Sector Protection Algorithm

Package Details Dimensions in inches.

32 Pin 0.1" Vertical-in-Line (VIL™) - 'V' Package

Minimum Order Product - Consult factory for further information.

32 Pin 0.6" Dual-in-Line (DIP) - 'S' Package

32 Pin Leadless Chip Carrier - 'W' Package

Minimum Order Product - Consult factory for further information.

32 Pin J Leaded Chip Carrier (JLCC) - 'J' Package

Screening**Military Screening Procedure**

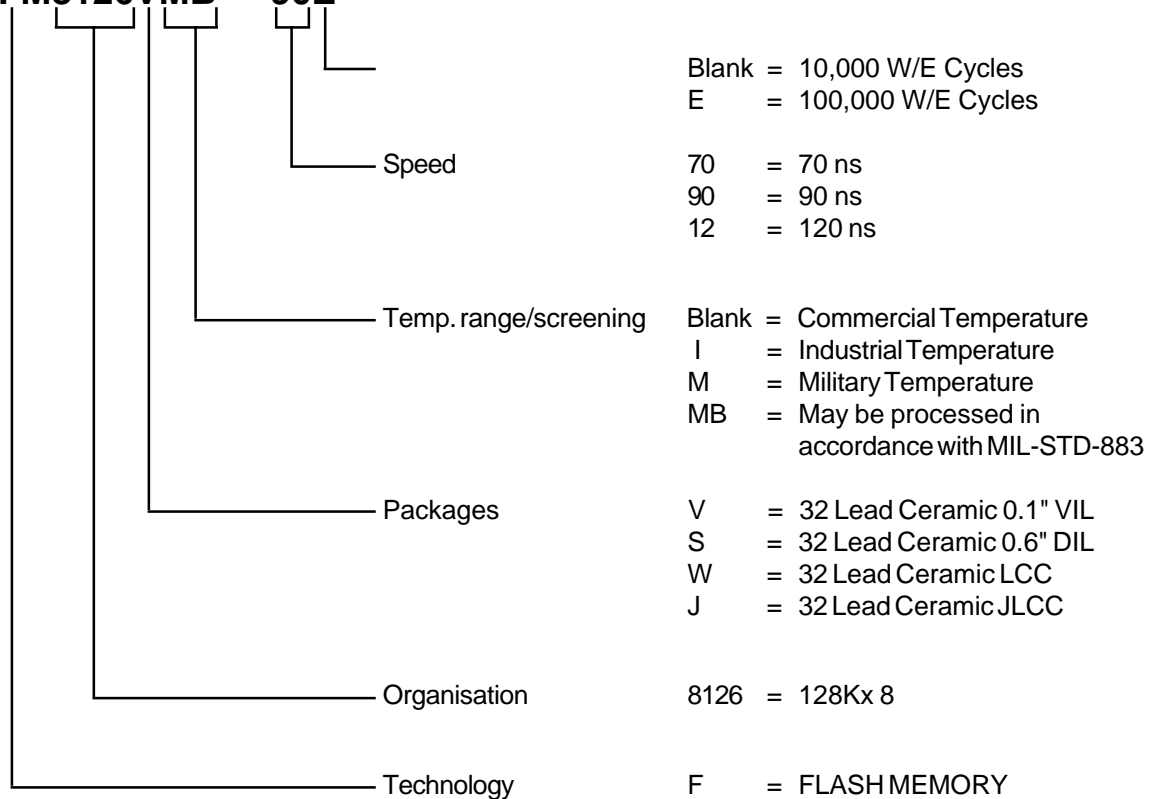

Component Screening Flow for high reliability product using methods from 5004.

MB COMPONENT SCREENING FLOW

<i>SCREEN</i>	<i>TESTMETHOD</i>	<i>LEVEL</i>
Mechanical		
Temperature cycle	1010 Condition C (10 Cycles, -65°C to +150°C)	100%
Constant acceleration	2001 Condition D (Y, only) (20,000g)	100%
Pre-Burn-in electrical	Per applicable device specifications at $T_A=+25^\circ\text{C}$	100%
Burn-in	Method 1015, Condition D, $T_A=+125^\circ\text{C}$, 160hrs min	100%
Endurance	As per internal specification	
Write Cycle endurance and Data Retention performance		
Final Electrical Tests	Per applicable Device Specification	
Static (dc)	a) @ $T_A=+25^\circ\text{C}$ and power supply extremes b) @ temperature and power supply extremes	100% 100%
Functional	a) @ $T_A=+25^\circ\text{C}$ and power supply extremes b) @ temperature and power supply extremes	100% 100%
Switching (ac)	a) @ $T_A=+25^\circ\text{C}$ and power supply extremes b) @ temperature and power supply extremes	100% 100%
Percent Defective allowable (PDA)	Calculated at post-burn-in at $T_A=+25^\circ\text{C}$	5%
Hermeticity	1014	
Fine	Condition A	100%
Gross	Condition C	100%
External Visual	2009 Per vendor or customer specification	100%
