Revision History

Rev. No.	History	Draft Date	Remark
0.0	1. Initial document.	June. 09. 1998	Preliminary
0.1	1. Changed DC parameters I_{CC}; from 450mA to 420mA at 150MHZ. I_{SB1}; from 10mA to 20mA, I_{SB2} ; from 10mA to 20mA.	Aug. 19. 1998	Preliminary
0.2	1. Changed t_{CD} from 4.0ns to 4.2ns at -75 2. Changed DC condition at Icc and parameters I_{SB1} ; from 20mA to 30mA, I_{SB2} ; from 20mA to 30mA.	Sep. 09. 1998	Preliminary
0.3	1. ADD 119BGA(7x17 Ball Grid Array Package) . 2. ADD x32 organization.	Oct. 15. 1998	Preliminary
0.4	Changed V_{OL} Max value from 0.2V to 0.4V at 2.5V I/O.	Dec. 23 .1998	Preliminary
1.0	1. Final Spec Release. 2. Remove x32 organization.	Jan. 29. 1999	Final
2.0	1. Remove V_{DDQ} Supply voltage(2.5V I/O)	Feb. 25. 1999	Final
3.0	1. Add V_{DDQ} Supply voltage(2.5V I/O)	May. 13. 1999	Final

256Kx36-Bit Pipelined NtRAM™

FEATURES

- 3.3V+0.165V/-0.165V Power Supply.
- I/O Supply Voltage 3.3V+0.165V/-0.165V for 3.3V I/O or 2.5V+0.4V/-0.125V for 2.5V I/O.
- Byte Writable Function.
- Enable clock and suspend operation.
- Single READ/WRITE control pin.
- Self-Timed Write Cycle.
- Three Chip Enable for simple depth expansion with no data contention only for TQFP.
- A interleaved burst or a linear burst mode.
- Asynchronous output enable control.
- Power Down mode.
- 100-TQFP-1420A /119BGA(7x17 Ball Grid Array Package).

GENERAL DESCRIPTION

The K7N803601M is 9,437,184 bits Synchronous Static SRAMs.

The NtRAM™, or No Turnaround Random Access Memory utilizes all the bandwidth in any combination of operating cycles. Address, data inputs, and all control signals except output enable and linear burst order are synchronized to input clock. Burst order control must be tied "High or Low".

Asynchronous inputs include the sleep mode enable(ZZ). Output Enable controls the outputs at any given time.

Write cycles are internally self-timed and initiated by the rising edge of the clock input. This feature eliminates complex off-chip write pulse generation and provides increased timing flexibility for incoming signals.

For read cycles, pipelined SRAM output data is temporarily stored by an edge triggered output register and then released to the output buffers at the next rising edge of clock.

The K7N803601M is implemented with SAMSUNG′s high performance CMOS technology and is available in 100pin TQFP and 119BGA packages. Multiple power and ground pins minimize ground bounce.

FUNCTION DESCRIPTION

The K7N803601M is N*t*RAM™ designed to sustain 100% bus bandwidth by eliminating turnaround cycle when there is transition from Read to Write, or vice versa.
All inputs (with the exception of $\overline{OE}$, $\overline{LBO}$ and ZZ) are synchronized to rising clock edges.

All read, write and deselect cycles are initiated by the ADV input. Subsequent burst addresses can be internally generated by the burst advance pin (ADV). ADV should be driven to Low once the device has been deselected in order to load a new address for next operation.

Clock Enable($\overline{CKE}$) pin allows the operation of the chip to be suspended as long as necessary. When $\overline{CKE}$ is high, all synchronous inputs are ignored and the internal device registers will hold their previous values.

N*t*RAM™ latches external address and initiates a cycle, when $\overline{CKE}$, ADV are driven to low and all three chip enables($\overline{CS_1}$, CS_2, $\overline{CS_2}$) are active .
Output Enable($\overline{OE}$) can be used to disable the output at any given time.

Read operation is initiated when at the rising edge of the clock, the address presented to the address inputs are latched in the address register, $\overline{CKE}$ is driven low, all three chip enables($\overline{CS_1}$, CS_2, $\overline{CS_2}$) are active, the write enable input signals $\overline{WE}$ are driven high, and ADV driven low.The internal array is read between the first rising edge and the second rising edge of the clock and the data is latched in the output register. At the second clock edge the data is driven out of the SRAM. Also during read operation $\overline{OE}$ must be driven low for the device to drive out the requested data.

Write operation occurs when $\overline{WE}$ is driven low at the rising edge of the clock. $\overline{BW}$[d:a] can be used for byte write operation. The pipe-lined N*t*RAM™ uses a late-late write cycle to utilize 100% of the bandwidth.
At the first rising edge of the clock, $\overline{WE}$ and address are registered, and the data associated with that address is required two cycle later.

Subsequent addresses are generated by ADV High for the burst access as shown below. The starting point of the burst seguence is provided by the external address. The burst address counter wraps around to its initial state upon completion.
The burst sequence is determined by the state of the $\overline{LBO}$ pin. When this pin is low, linear burst sequence is selected.
And when this pin is high, Interleaved burst sequence is selected.

During normal operation, ZZ must be driven low. When ZZ is driven high, the SRAM will enter a Power Sleep Mode after 2 cycles. At this time, internal state of the SRAM is preserved. When ZZ returns to low, the SRAM normally operates after 2 cycles of wake up time.

Notes : 1. An IGNORE CLOCK EDGE cycle is not shown is the above diagram. This is because CKE HIGH only blocks the clock(CLK) input and does not change the state of the device.
2. States change on the rising edge of the clock(CLK)

Notes : 1. All address inputs must meet the specified setup and hold times for all rising clock(CLK) edges when ADV is sampled low and $\overline{CS}$ is sampled low. All other synchronous inputs must meet the specified setup and hold times whenever this device is chip selected.
2. Chip selects must be valid at each rising edge of CLK(when ADV is Low) to remain enabled.
3. A write cycle is defined by $\overline{WE}$ low having been registered into the device at ADV Low, A Read cycle is defined by $\overline{WE}$ High with ADV Low, Both cases must meet setup and hold times.
4. To avoid bus contention, At a given voltage and temperature tCLZ is more than tHZC.
The specs as shown do not imply bus contention because tCLZ is a Min. parameter that is worst case at totally different test conditions (0°C,3.465V) than tCHZ, which is a Max. parameter(worst case at 70°C,3.135V)
It is not possible for two SRAMs on the same board to be at such different voltage and temperature.

SLEEP MODE

SLEEP MODE is a low current, power-down mode in which the device is deselected and current is reduced to I_{SB2}. The duration of SLEEP MODE is dictated by the length of time the ZZ is in a High state.
After entering SLEEP MODE, all inputs except ZZ become disabled and all outputs go to High-Z
The ZZ pin is an asynchronous, active high input that causes the device to enter SLEEP MODE.
When the ZZ pin becomes a logic High, I_{SB2} is guaranteed after the time t_{ZZI} is met. Any operation pending when entering SLEEP MODE is not guaranteed to successful complete. Therefore, SLEEP MODE (READ or WRITE) must not be initiated until valid pending operations are completed. similarly, when exiting SLEEP MODE during t_{PUS}, only a DESELECT or READ cycle should be given while the SRAM is transitioning out of SLEEP MODE.
