SHOCK AND VIBRATION RESISTANCE

The following test conditions are applied to assess the mechanical quality of the tube. These conditions are not intended to be used as normal operating conditions.

Shock

The tube is subjected 5 times in each of 4 positions to an acceleration of 500 g supplied by an NRL shock machine with the hammer lifted over an angle of 30°.

Vibration

The tube is subjected during 32 hours in each of 3 positions to a vibration frequency of 50 Hz with an acceleration of 2.5 g.

LIFE

Production samples are tested during 10 000 hours under the following conditions:

Anode supply voltage	V_{ba}	170 V
Grid supply voltage	$+V_{bg}$	9 V
Cathode resistor	R_k	820 Ω

¹⁾ Measured between the tube pin connected to the relevant electrode and a metal reference plane placed against the tube bottom. The relevant pin and the reference plane are connected to the measuring device so that the minimum distance is obtained between these two connecting points. The remaining tube pins are connected to the reference plane with a negligible impedance. The tube is screened by a cylinder with an internal diameter of 23 mm placed on the reference plane.

LIMITING VALUES (Absolute max. rating system)

Anode voltage	V_{a0}	max.	400 V
	V_a	max.	200 V
Anode dissipation	W_a	max.	2.6 W
Cathode current	I_k	max.	16.5 mA
Grid voltage	$-V_g$	max.	50 V
Grid dissipation	W_g	max.	50 mW
Grid resistor	R_g	max.	1 M Ω
Cathode resistor $R_k = 100 \Omega$

Heater voltage: The average heater voltage should be 6.3 V.

Variation of the heater voltage exceeding the range of 6.0 V to 6.6 V will shorten the tube life.
