## 12-BIT, 4-MSPS LOW POWER SAR ANALOG-TO-DIGITAL CONVERTER

## FEATURES

- 4 MHz Sample Rate, 12-Bit Resolution
- Zero Latency
- Unipolar, Pseudo Differential Input, Range:
- 0 V to 2.5 V
- High Speed Parallel Interface
- 71 dB SNR and -88.5 dB THD at $1 \mathrm{MHz} \mathrm{I/P}$
- Power Dissipation 95 mW at 4 MSPS
- Nap Mode (10 mW Power Dissipation)
- Power Down ( $10 \mu \mathrm{~W}$ )
- Internal Reference
- Internal Reference Buffer
- 48-Pin TQFP and QFN Packages

## DESCRIPTION

The ADS7881 is a 12 -bit 4-MSPS A-to-D converter with $2.5-\mathrm{V}$ internal reference. The device includes a capacitor based SAR A/D converter with inherent sample and hold. The device offers a 12-bit parallel interface with an additional byte mode that provides easy interface with 8-bit processors. The device has a pseudo-differential input stage.

## APPLICATIONS

- Optical Networking (DWDM, MEMS Based Switching)
- Spectrum Analyzers
- High Speed Data Acquisition Systems
- High Speed Close-Loop Systems
- Telecommunication
- Ultra-Sound Detection

The -IN swing of $\pm 200 \mathrm{mV}$ is useful to compensate for ground voltage mismatch between the ADC and sensor and also to cancel common-mode noise. With nap mode enabled, the device operates at lower power when used at lower conversion rates. The device is available in 48-pin TQFP and QFN packages.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## ORDERING INFORMATION

| MODEL | MAXIMUM INTEGRAL LINEARITY (LSB) | MAXIMUM DIFFERENTIAL LINEARITY (LSB) | NO MISSING CODES AT RESOLUTION (BIT) | PACKAGE TYPE | PACKAGE DESIGNATOR | TEMPERATURE RANGE | ORDERING INFORMATION | TRANSPORT MEDIA QUANTITY |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ADS7881 | $\pm 1$ | $\pm 1$ | 12 | $\begin{aligned} & \text { 48-Pin } \\ & \text { TQFP } \end{aligned}$ | PFB | $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ | ADS7881IPFBT | Tape and reel $250$ |
|  |  |  |  |  |  |  | ADS7881IPFBR | Tape and reel 1000 |
|  | $\pm 1$ | $\pm 1$ | 12 | $\begin{aligned} & \text { 48-Pin } \\ & \text { QFN } \end{aligned}$ | RGZ | $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ | ADS7881IRGZT | Tape and reel 250 |
|  |  |  |  |  |  |  | ADS7881IRGZR | Tape and reel 2500 |

NOTE: For most current package and ordering information, see the Package Option Addendum at the end of this document, or see the TI web site at www.ti.com.

## ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range(1)

|  |  | UNIT |
| :---: | :---: | :---: |
| +IN to AGND |  | -0.3 V to + VA +0.1 V |
| -IN to AGND |  | -0.3 V to 0.5 V |
| +VA to AGND |  | -0.3 V to 7 V |
| +VBD to BDGND |  | -0.3 V to 7 V |
| Digital input voltage to GND |  | -0.3 V to (+VBD +0.3 V ) |
| Digital output to GND |  | -0.3 V to (+VBD +0.3 V ) |
| Operating temperature range |  | $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ |
| Storage temperature range |  | $-65^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ |
| Junction temperature (TJmax) |  | $150^{\circ} \mathrm{C}$ |
| QFP and OFN packag | Power dissipation | $\left(\mathrm{T}_{J} \mathrm{Max}-\mathrm{T}_{\mathrm{A}}\right) / \theta_{\text {JA }}$ |
| QFP and QFN packages | $\theta$ JA Thermal impedance | $86^{\circ} \mathrm{C} / \mathrm{W}$ |
|  | Vapor phase ( 60 sec ) | $215^{\circ} \mathrm{C}$ |
| ad temperature, soldering | Infrared (15 sec) | $220^{\circ} \mathrm{C}$ |

(1) Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

## DESCRIPTION AND TIMING DIAGRAMS

## SAMPLING AND CONVERSION START

There are three ways to start sampling. The rising edge of $\overline{C O N V S T}$ starts sampling with $\overline{\mathrm{CS}}$ and BUSY being low (see Figure 1) or it can be started with the falling edge of $\overline{C S}$ when CONVST is high and BUSY is low (see Figure 2). Sampling can also be started with an internal conversion end (before BUSY falling edge) with $\overline{C S}$ being low and CONVST high before an internal conversion end (see Figure 3). Also refer to the section DEVICE OPERATION AND DATA READ IN BACK-TO-BACK CONVERSION for more details.

A conversion can be started two ways (a conversion start is the end of sampling). Either with the falling edge of $\overline{C O N V S T}$ when $\overline{C S}$ is low (see Figure 1) or the falling edge of $\overline{C S}$ when CONVST is low (see Figure 2). A clean and low jitter falling edge of these respective signals triggers a conversion start and is important to the performance of the converter. The BUSY pin is brought high immediately following the CONVST falling edge. BUSY stays high throughout the conversion process and returns low when the conversion has ended.

Figure 1. Sampling and Conversion Start Control With CONVST Pin

Figure 2. Sampling and Conversion Start Control With $\overline{\mathrm{CS}}$ Pin

Figure 3. Sampling Start With $\overline{\mathrm{CS}}$ Low and $\overline{\text { CONVST High (Back-to-Back) }}$

## CONVERSION ABORT

The falling edge of $\overline{\mathrm{CS}}$ aborts the conversion while BUSY is high and $\overline{\text { CONVST }}$ is high (see Figure 4). The device outputs FEO (hex) to indicate a conversion abort.

Figure 4. Conversion Abort

## DATA READ

Two conditions need to be satisfied for a read operation. Data appears on the D11 through D0 pins (with D11 MSB ) when both $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are low. Figure 5 and Figure 6 illustrate the device read operation. The bus is three-stated if any one of the signals is high.

Figure 5. Read Control Via $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$
There are two output formats available. Twelve bit data appears on the bus during a read operation while BYTE is low. When BYTE is high, the lower byte (D3 through D0 followed by all zeroes) appears on the data bus with D3 in the MSB. This feature is useful for interfacing with eight bit microprocessors and microcontrollers.

Figure 6. Read Control Via $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ Tied to BDGND

## DEVICE OPERATION AND DATA READ IN BACK-TO-BACK CONVERSION

The following two figures illustrate device operation in back-to-back conversion mode. It is possible to operate the device at any throughput in this mode, but this is the only mode in which the device can be operated at throughputs exceeding 3.5 MSPS.
A conversion starts on the CONVST falling edge. The BUSY output goes high after a delay ( $t_{\mathrm{d} 2}$ ). Note that care must be taken not to abort the conversion (see Figure 4) apart from timing restrictions shown in Figure 7 and Figure 8. The conversion ends within the conversion time, $t_{\text {(conv), }}$, after the CONVST falling edge. The new acquisition can be immediately started without waiting for the BUSY signal to go low. This can be ensured with a CONVST high pulse width that is more than or equal $\left.\mathrm{to}^{\left(\mathrm{t}_{0}-\mathrm{t}\right.} \mathrm{t}_{(\mathrm{conv})}+10 \mathrm{nsec}\right)$ which is $\mathrm{t}_{\mathrm{w} 4}$ for a $4-\mathrm{MHz}$ operation.

Figure 7. Back-To-Back Operation With $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ Low

Figure 8. Back-To-Back operation With $\overline{\mathrm{CS}}$ Toggling and $\overline{\mathrm{RD}}$ Low

## NAP MODE

The device can be put in nap mode following the sequences shown in Figure 9. This provides substantial power saving while operating at lower sampling rates.

While operating the device at throughput rates lower than 3.2 MSPS, $\overline{\text { A_PWD }}$ can be held low (see Figure 9). In this condition, the device goes into the nap state immediately after BUSY goes low and remains in that state until the next sampling starts. The minimum acquisition time is 60 nsec more than $\mathrm{t}_{(\mathrm{acq})}$ as defined in the timing requirements section.

Alternately, $\overline{\text { A_PWD }}$ can be toggled any time during operation (see Figure 10). This is useful when the system acquires data at the maximum conversion speed for some period of time (back-to-back conversion) and it does not acquire data for some time while the acquired data is being processed. During this period, the device can be put in the nap state to save power. The device remains in the nap state as long as $\overline{A_{-} P W D}$ is low with BUSY being low and sampling has not started. The minimum acquisition time for the first sampling after the nap state is 60 nsec more than $\mathrm{t}_{(\mathrm{acq})}$ as defined in the timing requirements section.

NOTE: The SAMPLE (Internal) signal is generated as described in the Sampling and Conversion Start section.

Figure 9. Device Operation While $\overline{\mathbf{A} \_P W D}$ is Held Low

NOTE:

## POWERDOWN/RESET

A low level on the $\overline{\mathrm{PWD}} / \overline{\mathrm{RST}}$ pin puts the device in the powerdown phase. This is an asynchronous signal. As shown in Figure 11, the device is in the reset phase for the first $t_{w 6}$ period after a high-to-low transition of $\overline{P W D} / \overline{\mathrm{RST}}$. During this period the output code is FEO (hex) to indicate that the device is in the reset phase. The device powers down if the PWD/RST pin continues to be low for a period of more than $t_{w 7}$. Data is not valid for the first four conversions after a power-up (see Figure 11) or an end of reset (see Figure 12). The device is initialized during the first four conversions.

## PRINCIPLES OF OPERATION

The ADS7881 is a member of a family of high-speed successive approximation register (SAR) analog-to-digital converters (ADC). The architecture is based on charge redistribution, which inherently includes a sample/hold function.
The conversion clock is generated internally. The conversion time is 200 ns max (at $5 \mathrm{~V}+\mathrm{VBD}$ ).
The analog input is provided to two input pins: $+\mathbb{N}$ and $-\mathbb{I N}$. (Note that this is pseudo differential input and there are restrictions on -IN voltage range.) When a conversion is initiated, the difference voltage between these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

## REFERENCE

The ADS7881 has a built-in 2.5-V (nominal value) reference but can operate with an external reference. When an internal reference is used, pin 2 (REFOUT) should be connected to pin 1 (REFIN) with an $0.1-\mu \mathrm{F}$ decoupling capacitor and a $1-\mu \mathrm{F}$ storage capacitor between pin 2 (REFOUT) and pins 47, 48 (REFM). The internal reference of the converter is buffered. There is also a buffer from REFIN to CDAC. This buffer provides isolation between the external reference and the CDAC and also recharges the CDAC during conversion. It is essential to decouple REFOUT to AGND with a $0.1-\mu \mathrm{F}$ capacitor while the device operates with an external reference.

## ANALOG INPUT

When the converter enters hold mode, the voltage difference between the $+\mathbb{N}$ and $-\mathbb{N}$ inputs is captured on the internal capacitor array. The voltage on the -IN input is limited to between -0.2 V and 0.2 V , thus allowing the input to reject a small signal which is common to both the $+\mathbb{N}$ and $-\mathbb{I N}$ inputs. The $+I N$ input has a range of -0.2 V to $\left(+\mathrm{V}_{\text {ref }}+0.2 \mathrm{~V}\right)$. The input span ( $+\mathrm{IN}-(-\mathrm{IN})$ ) is limited from 0 V to VREF.

The input current on the analog inputs depends upon a number of factors: sample rate, input voltage, signal frequency, and source impedance. Essentially, the current into the ADS7881 charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current (this may not happen when a signal is moving continuously). The source of the analog input voltage must be able to charge the input capacitance ( 27 pF ) to better than a 12-bit settling level with a step input within the acquisition time of the device. The step size can be selected equal to the maximum voltage difference between two consecutive samples at the maximum signal frequency. (Refer to Figure 39 for the suggested input circuit.) When the converter goes into hold mode, the input impedance is greater than $1 \mathrm{G} \Omega$.

Care must be taken regarding the absolute analog input voltage. To maintain the linearity of the converter, both -IN and +IN inputs should be within the limits specified. Outside of these ranges, the converter's linearity may not meet specifications.
Care should be taken to ensure that +IN and -IN see the same impedance to the respective sources. (For example, both $+\mathbb{N}$ and $-\mathbb{I N}$ are connected to a decoupling capacitor through a $21-\Omega$ resistor as shown in Figure 39.) If this is not observed, the two inputs could have different settling times. This may result in an offset error, gain error, or linearity error which changes with temperature and input voltage.

## DIGITAL INTERFACE

## TIMING AND CONTROL

Refer to the SAMPLING AND CONVERSION START section and the CONVERSION ABORT section.

## READING DATA

The ADS7881 outputs full parallel data in straight binary format as shown in Table 1. The parallel output is active when $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are both low. There is a minimal quiet sampling period requirement around the falling edge of CONVST as stated in the timing requirements section. Data reads or bus three-state operations should not be attempted within this period. Any other combination of CS and RD three-states the parallel output. Refer to Table 1 for ideal output codes.

Table 1. Ideal Input Voltages and Output Codes(1)

| DESCRIPTION | ANALOG VALUE | BINARY CODE | HEX CODE |
| :--- | :--- | :--- | :--- |
| Full scale | $\mathrm{V}_{\text {ref }}-1 \mathrm{LSB}$ | 111111111111 | FFF |
| Midscale | $\mathrm{V}_{\text {ref }} / 2$ | 100000000000 | 800 |
| Midscale -1 LSB | $\mathrm{V}_{\text {ref }} / 2-1 \mathrm{LSB}$ | 011111111111 | 7FF |
| Zero | 0 V | 000000000000 | 000 |

(1) Full-scale range $=\mathrm{V}_{\text {ref }}$ and least significant bit $(\mathrm{LSB})=\mathrm{V}_{\text {ref }} / 4096$

The output data appears as a full 12-bit word (D11-D0) on pins DB11 - DB0 (MSB-LSB) if BYTE is low.
READING THE DATA IN BYTE MODE
The result can also be read on an 8 -bit bus for convenience by using pins DB11-DB4. In this case two reads are necessary; the first as before, leaving BYTE low and reading the 8 most significant bits on pins DB11-DB4, and then bringing BYTE high. When BYTE is high, the lower bits (D3-D0) followed by all zeros are on pins DB11 - DB4 (refer to Table 2).

These multi-word read operations can be performed with multiple active $\overline{\mathrm{RD}}$ signals (toggling) or with $\overline{\mathrm{RD}}$ tied low for simplicity.

Table 2. Conversion Data Read Out

| BYTE |  | DATA READ OUT |  |
| :--- | :--- | :--- | :---: |
|  |  | DB3 - DB0 |  |
| High | D3 - D0, 0000 | All zeroes |  |
| Low | D11 - D4 | D3 - D0 |  |

Also refer to the DATA READ and DEVICE OPERATION AND DATA READ IN BACK-TO-BACK CONVERSION sections for more details.

## Reset

Refer to the POWERDOWN/RESET section for the device reset sequence.
It is recommended to reset the device after power on. A reset can be issued once the power has reached $95 \%$ of its final value.
$\overline{\mathrm{PWD}} / \overline{\mathrm{RST}}$ is an asynchronous active low input signal. A current conversion is aborted no later than 45 ns after the converter is in the reset mode. In addition, the device outputs a FEO code to indicate a reset condition. The converter returns back to normal operation mode immediately after the $\overline{\text { PWD }} / \overline{\mathrm{RST}}$ input is brought high.

Data is not valid for the first four conversions after a device reset.

## Powerdown

Refer to the POWERDOWN/RESET section for the device powerdown sequence.
The device enters powerdown mode if a $\overline{\mathrm{PWD}} / \overline{\mathrm{RST}}$ low duration is extended for more than a period of $\mathrm{t}_{\mathrm{w} 7}$.
The converter goes back to normal operation mode no later than a period of $t_{d 13}$ after the $\overline{\mathrm{PWD}} / \overline{\mathrm{RST}}$ input is brought high.

After this period, normal conversion and sampling operation can be started as discussed in previous sections. Data is not valid for the first four conversions after a device reset.

## Nap Mode

Refer to the NAP MODE section in the DESCRIPTION AND TIMING DIAGRAMS section for information.

SLAS400B - SEPTEMBER 2003 - REVISED NOVEMBER 2005

## APPLICATION INFORMATION

## LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS7881 circuitry.
As the ADS7881 offers single-supply operation, it is often used in close proximity with digital logic, micro-controllers, microprocessors, and digital signal processors. The more digital logic present in the design and the higher the switching speed, the more difficult it is to achieve acceptable performance from the converter.
The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections, and digital inputs that occur just prior to the end of sampling (within quiet sampling time) and just prior to latching the output of the analog comparator during the conversion phase. Thus, driving any single conversion for an $n$-bit SAR converter, there are $\mathrm{n}+1$ windows in which large external transient voltages can affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, or high power devices.

The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event.

On average, the ADS7881 draws very little current from an external reference as the reference voltage is internally buffered. If the reference voltage is external and originates from an op amp, make sure that it can drive the bypass capacitor or capacitors without oscillation. A $0.1-\mu \mathrm{F}$ bypass capacitor and $1-\mu \mathrm{F}$ storage capacitor are recommended from REFIN (pin 1) directly to REFM (pin 48).

The AGND and BDGND pins should be connected to a clean ground point. In all cases, this should be the analog ground. Avoid connections which are too close to the grounding point of a micro-controller or digital signal processor. If required, run a ground trace directly from the converter to the power supply entry point. The ideal layout consists of an analog ground plane dedicated to the converter and associated analog circuitry.

As with the AGND connections, +VA should be connected to a $5-\mathrm{V}$ power supply plane that is separate from the connection for +VBD and digital logic until they are connected at the power entry point onto the PCB. Power to the ADS7881 should be clean and well bypassed. A $0.1-\mu \mathrm{F}$ ceramic bypass capacitor should be placed as close to the device as possible. See Table 3 for the placement of capacitor. In addition to a $0.1-\mu \mathrm{F}$ capacitor, a $1-\mu \mathrm{F}$ capacitor is recommended. In some situations, additional bypassing may be required, such as a $100-\mu \mathrm{F}$ electrolytic capacitor or even a Pi filter made up of inductors and capacitors, all designed to essentially low-pass filter the 5-V supply, removing the high frequency noise.

Table 3. Power Supply Decoupling Capacitor Placement

| POWER SUPPLY PLANE | CONVERTER ANALOG SIDE | CONVERTER DIGITAL SIDE |
| :--- | :--- | :--- |
| SUPPLY PINS |  | $(24,25),(34,35)$ |
| Pairs of pins that require a shortest path to decoupling <br> capacitors | $(4,5),(9,8),(10,11),(13,15),(43,44)(46,45)$ | $(14,12$ |
| Pins that require no decoupling | 12 |  |
