ADS8365

## 16-Bit, 250kSPS, 6-Channel, Simultaneous Sampling SAR ANALOG-TO-DIGITAL CONVERTERS

## FEATURES

- Six Input Channels
- Fully Differential Inputs
- Six Independent 16-Bit ADCs
- $4 \mu \mathrm{~s}$ Total Throughput per Channel
- Low Power:

200mW in Normal Mode
5 mW in Nap Mode
$50 \mu$ W in Power-Down Mode

- TQFP-64 Package Package

## APPLICATIONS

## - Motor Control

- Multi-Axis Positioning Systems
- 3-Phase Power Control

## DESCRIPTION

The ADS8365 includes six, 16-bit, 250kSPS analog-to-digital converters (ADCs) with six fully differential input channels grouped into three pairs for high-speed simultaneous signal acquisition. Inputs to the sample-and-hold amplifiers are fully differential and are maintained differential to the input of the ADC. This architecture provides excellent common-mode rejection of 80 dB at 50 kHz , which is important in high-noise environments.
The ADS8365 offers a flexible, high-speed parallel interface with a direct address mode, a cycle, and a FIFO mode. The output data for each channel is available as a 16-bit word.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet. All trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## ORDERING INFORMATION ${ }^{(1)}$

| PRODUCT | MAXIMUM INTEGRAL LINEARITY ERROR (LSB) | NO MISSING CODES ERROR (LSB) | PACKAGELEAD | PACKAGE DESIGNATOR | SPECIFIED TEMPERATURE RANGE | PACKAGE MARKING | ORDERING NUMBER | TRANSPORT MEDIA, QUANTITY |

|  |  |  |  |  |  |  | ADS8365IPAG | Tray, 160 |
| ADS8365 | $\pm 4$ | 14 | TQFP-64 | PAG | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ | ADS8365AI | ADS8365IPAGR | Tape and Reel, 1500 |

(1) For the most current package and ordering information, see the Package Option Addendum located at the end of this data sheet, or see the TI website at www.ti.com.

## ABSOLUTE MAXIMUM RATINGS ${ }^{(1)}$

over operating free-air temperature range (unless otherwise noted)

|  | ADS8365 | UNIT |
| :---: | :---: | :---: |
| Supply voltage, $A G N D$ to $A V_{D D}$ | -0.3 to 6 | V |
| Supply voltage, BGND to $\mathrm{BV}_{\mathrm{DD}}$ | -0.3 to 6 | V |
| Analog input voltage range | AGND - 0.3 to $A V_{D D}+0.3$ | V |
| Reference input voltage range | AGND -0.3 to $\mathrm{AV}_{\mathrm{DD}}+0.3$ | V |
| Digital input voltage range | BGND - 0.3 to $\mathrm{BV}_{\mathrm{DD}}+0.3$ | V |
| Ground voltage differences, AGND to BGND | $\pm 0.3$ | V |
| Voltage differences, $\mathrm{BV}_{\text {DD }}$ to AGND | -0.3 to 6 | V |
| Input current to any pin except supply | -20 to 20 | mA |
| Power dissipation | See Dissipation Ratings Table |  |
| Operating virtual junction temperature range, $\mathrm{T}_{J}$ | -40 to +150 | ${ }^{\circ} \mathrm{C}$ |
| Operating free-air temperature range, $\mathrm{T}_{\mathrm{A}}$ | -40 to +85 | ${ }^{\circ} \mathrm{C}$ |
| Storage temperature range, $\mathrm{T}_{\text {STG }}$ | -65 to +150 | ${ }^{\circ} \mathrm{C}$ |

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions is not implied. Exposure to absolute-maximum rated conditions for extended periods may affect device reliability.

## INTRODUCTION

The ADS8365 is a high-speed, low-power, six-channel simultaneous sampling and converting, 16 -bit ADC that operates from a single +5 V supply. The input channels are fully differential with a typical common-mode rejection of 80 dB . The ADS8365 contains six $4 \mu$ s successive approximation ADCs, six differential sample-and-hold amplifiers, an internal +2.5 V reference with $\mathrm{REF}_{\text {IN }}$ and $R E F_{\text {Out }}$ pins, and a high-speed parallel interface. There are six analog inputs that are grouped into three channel pairs (A, B, and C). There are six ADCs, one for each input that can be sampled and converted simultaneously, thus preserving the relative phase information of the signals on both analog inputs. Each pair of channels has a hold signal (HOLDA, HOLDB, and HOLDC) to allow simultaneous sampling on each channel pair, on four or on all six channels. The part accepts a differential analog input voltage in the range of $-\mathrm{V}_{\text {REF }}$ to $+\mathrm{V}_{\mathrm{REF}}$, centered on the common-mode voltage (see the Analog Input section). The ADS8365 also accepts bipolar input ranges when a level shift circuit is used at the front end (see Figure 26).
A conversion is initiated on the ADS8365 by bringing the HOLDX pin low for a minimum of 20 ns. HOLDX low places the sample-and-hold amplifiers of the X channels in the hold state simultaneously and the conversion process is started on each channel. The EOC output goes low for half a clock cycle when the conversion is latched into the output register. The data can be read from the parallel output bus following the conversion by bringing both $\overline{\mathrm{RD}}$ and $\overline{\mathrm{CS}}$ low. Conversion time for the ADS8365 is $3.2 \mu \mathrm{~s}$ when a 5 MHz external clock is used. The corresponding acquisition time is $0.8 \mu \mathrm{~s}$. To achieve the maximum output data rate ( 250 kSPS ), the read function can be performed during the next conversion. NOTE: This mode of operation is described in more detail in the Timing and Control section of this data sheet.

## SAMPLE AND HOLD

The sample-and-hold amplifiers on the ADS8365 allow the ADCs to accurately convert an input sine wave of full-scale amplitude to 16 -bit resolution. The input bandwidth of the sample-and-hold amplifiers is greater than the Nyquist rate (Nyquist $=1 / 2$ of the sampling rate) of the ADC, even when the ADC is operated at its maximum throughput rate of 250kSPS. The typical small-signal bandwidth of the sample-and-hold amplifiers is 10 MHz . Typical aperture delay time (or the time it takes for the ADS8365 to switch from the sample to the hold mode following the negative edge of the HOLDX signal) is

5 ns . The average delta of repeated aperture delay values (also known as aperture jitter) is typically 50 ps . These specifications reflect the ability of the ADS8365 to capture ac input signals accurately at the exact same moment in time.

## REFERENCE

Under normal operation, REF OUt (pin 61) can be directly connected to $\mathrm{REF}_{\mathrm{IN}}$ (pin 62) to provide an internal +2.5 V reference to the ADS8365. The ADS8365 can operate, however, with an external reference in the range of 1.5 V to 2.6 V , for a corresponding full-scale range of 3.0 V to 5.2 V , as long as the input does not exceed the $\mathrm{AV}_{\mathrm{DD}}+0.3 \mathrm{~V}$ limit.

The reference output of the ADS8365 has an impedance of $2 \mathrm{k} \Omega$. The high impedance reference input can be driven directly. For an external resistive load, an additional buffer is required. A load capacitance of $0.1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ should be applied to the reference output to minimize noise. If an external reference is used, the three input buffers provide isolation between the external reference and the CDACs. These buffers are also used to recharge all the capacitors of all CDACs during conversion.

## ANALOG INPUT

The analog input is bipolar and fully differential. There are two general methods of driving the analog input of the ADS8365: single-ended or differential, as shown in Figure 21 and Figure 22 When the input is single-ended, the $-\operatorname{IN}$ input is held at the common-mode voltage. The +IN input swings around the same common voltage and the peak-to-peak amplitude is the (common-mode $+\mathrm{V}_{\text {REF }}$ ) and the (common-mode $-\mathrm{V}_{\text {REF }}$ ). The value of $\mathrm{V}_{\text {REF }}$ determines the range over which the common-mode voltage may vary (see Figure 23).

Figure 21. Methods of Driving the ADS8365 Single-Ended or Differential

NOTES:
Common-mode voltage $($ Differential mode $)=\frac{(+I N)+(-I N)}{2}$. Common-mode voltage (Single-ended mode) $=-\mathrm{IN}$
The maximum differential voltage between $+I N$ and $-I N$ of the ADS8365 is $V_{\text {REF }}$. See Figure 23 and Figure 24 for a further explanation of the common voltage range for single-ended and differential inputs.

Figure 22. Using the ADS8365 in the Single-Ended and Differential Input Modes

Figure 23. Single-Ended Input: Common-Mode Voltage Range vs $\mathrm{V}_{\text {REF }}$

When the input is differential, the amplitude of the input is the difference between the +IN and -IN input, or: $(+I N)-(-I N)$. The peak-to-peak amplitude of each input is $\pm 1 / 2 \mathrm{~V}_{\text {REF }}$ around this common voltage. However, since the inputs are $180^{\circ}$ out-of-phase, the peak-to-peak amplitude of the differential voltage is $+\mathrm{V}_{\text {REF }}$ to $-\mathrm{V}_{\text {REF }}$. The value of $\mathrm{V}_{\text {REF }}$ also determines the range of the voltage that may be common to both inputs, as shown in Figure 24.

Figure 24. Differential Input: Common-Mode Voltage Range vs $\mathrm{V}_{\text {REF }}$

In each case, care should be taken to ensure that the output impedance of the sources driving the +IN and -IN inputs are matched. Often, a small capacitor (20pF) between the positive and negative input helps to match the impedance. Otherwise, a mismatch may result in offset error, which will change with both temperature and input voltage.
The input current on the analog inputs depends on a number of factors, such as sample rate or input
voltage. Essentially, the current into the ADS8365 charges the internal capacitor array during the sampling period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance ( 25 pF ) to a 16 -bit settling level within three clock cycles if the minimum acquisition time is used. When the converter goes into the hold mode, the input impedance is greater than $1 G \Omega$. Care must be taken regarding the absolute analog input voltage. The +IN and -IN inputs should always remain within the range of $A G N D-0.3 \mathrm{~V}$ to $\mathrm{AV}_{\mathrm{DD}}+$ 0.3 V .

The OPA365 is a good choice for driving the analog inputs in a 5 V , single-supply application.

## TRANSITION NOISE

The transition noise of the ADS8365 itself is low, as shown in Figure 25 These histograms were generated by applying a low-noise dc input and initiating 8000 conversions. The digital output of the ADC will vary in output code due to the internal noise of the ADS8365; this feature is true for all 16-bit, successive approximation register (SAR) type ADCs. Using a histogram to plot the output codes, the distribution should appear bell-shaped, with the peak of the bell curve representing the nominal code for the input value. The $\pm 1 \sigma, \pm 2 \sigma$, and $\pm 3 \sigma$ distributions represent the $68.3 \%, 95.5 \%$, and $99.7 \%$, respectively, of all codes. The transition noise can be calculated by dividing the number of codes measured by 6 , yielding the $\pm 3 \sigma$ distribution, or $99.7 \%$, of all codes. Statistically, up to three codes could fall outside the distribution when executing 1000 conversions. Remember, in order to achieve this low-noise performance, the peak-to-peak noise of the input signal and reference must be $<50 \mu \mathrm{~V}$.

Figure 25. 8000 Conversion Histogram of a DC Input

## BIPOLAR INPUTS

The differential inputs of the ADS8365 were designed to accept bipolar inputs ( $-\mathrm{V}_{\text {REF }}$ and $+\mathrm{V}_{\text {REF }}$ ) around the common-mode voltage ( 2.5 V ), which corresponds to a 0 V to 5 V input range with a 2.5 V reference. By using a simple op amp circuit featuring four, high-precision external resistors, the ADS8365 can be configured to accept a bipolar input range. The conventional $\pm 2.5 \mathrm{~V}, \pm 5 \mathrm{~V}$, and $\pm 10 \mathrm{~V}$ input ranges could be interfaced to the ADS8365 using the resistor values shown in Figure 26.

Figure 26. Level Shift Circuit for Bipolar Input Ranges

## TIMING AND CONTROL

The ADS8365 uses an external clock (CLK, pin 28) that controls the conversion rate of the CDAC. With a 5 MHz external clock, the ADC sampling rate is 250kSPS which corresponds to a $4 \mu \mathrm{~s}$ maximum throughput time. Acquisition and conversion take a total of 20 clock cycles.

## THEORY OF OPERATION

The ADS8365 contains six 16-bit ADCs that can operate simultaneously in pairs. The three hold signals (HOLDA, HOLDB, and HOLDC) initiate the conversion on the specific channels. A simultaneous hold on all six channels can occur with all three hold signals strobed together. The converted values are saved in six registers. For each read operation, the ADS8365 outputs 16 bits of information ( 16 data or 3 channel address, data valid, and some synchronization information). The address/mode signals (A0, A1, and A2) select how the data are read from the ADS8365. These address/mode signals can define a selection of a single channel, a cycle mode that cycles through all channels, or a FIFO mode that sequences the data determined by the order of the hold signals. The FIFO mode will allow the six registers to be used by a single-channel pair; therefore, three locations for CH X0 and three locations for CH X1 can be updated before they are read from the device.

## EXPLANATION OF CLOCK, RESET, FD, AND EOC PINS

Clock An external clock has to be provided for the ADS8365. The maximum clock frequency is 5 MHz . The minimum clock cycle is 200 ns (see Figure 1, $\mathrm{t}_{\mathrm{c} 1}$ ), and the clock has to remain high (Figure 1, $\mathrm{t}_{\mathrm{w}_{1}}$ ) or low for at least 60 ns .
RESET Bringing the RESET signal low will reset the ADS8365. Resetting clears the control register
and all the output registers, aborts any conversion in process, and closes the sampling switches. The reset signal must stay low for at least 20 ns (see Figure 27, $\mathrm{t}_{\mathrm{w} 4}$ ). The reset signal should be back high for at least 20 ns (Figure 27, $\mathrm{t}_{\mathrm{D} 2}$ ) before starting the next conversion (negative hold edge).
EOC End of conversion goes low when new data from the internal ADC are latched into the output registers, which usually happens 16.5 clock cycles after hold initiated the conversion. It remains low for half a clock cycle. If more than one channel pair is converted simultaneously, the A-channels get stored to the registers first ( 16.5 clock cycles after hold), followed by the B-channels one clock cycle later, and finally the C-channels another clock cycle later. If a reading (both $\overline{\mathrm{RD}}$ and $\overline{\mathrm{CS}}$ are low) is in process, then the latch process is delayed until the read operation is finished.

FD First data or A0 data are high if channel A0 is chosen to be read next. In FIFO mode, the channel (XO) that is written to the FIFO first is latched into the AO register. For example, when the FIFO is empty, FD is 0 . The first result latched into the FIFO register A0 is, therefore, chosen to be read next, and FD rises. After the first channel is read (one to three read cycles, depending on BYTE and ADD), FD goes low again.

Figure 27. Start of the Conversion

## START OF A CONVERSION AND READING DATA

By bringing one, two, or all three of the HOLDX signals low, the input data of the corresponding channel $X$ are immediately placed in the hold mode (5ns). The conversion of this channel $X$ follows with the next rising edge of clock. If it is important to detect a hold command during a certain clock-cycle, then the falling edge of the hold signal has to occur at least 10 ns before the rising edge of clock, as shown in Figure 27, $\mathrm{t}_{\mathrm{D}}$. The hold signal can remain low without initiating a new conversion. The hold signal must be high for at least 15 ns (as shown in Figure 27, $\mathrm{t}_{\mathrm{w}}$ ) before it is brought low again, and hold must stay low for at least 20 ns (Figure 27, $\mathrm{t}_{\mathrm{w}}$ ).
Once a particular hold signal goes low, further impulses of this hold signal are ignored until the conversion is finished or the device is reset. When the conversion is finished (after 16 clock cycles) the sampling switches close and sample the selected channel. The start of the next conversion must be delayed to allow the input capacitor of the ADS8365 to be fully charged. This delay time depends on the driving amplifier, but should be at least 800 ns .

The ADS8365 can also convert one channel continuously (see Figure 28). Therefore, HOLDA and HOLDC are kept high all the time. To gain acquisition time, the falling edge of HOLDB takes place just before the rising edge of clock. One conversion requires 20 clock cycles. Here, data are read after the next conversion is initiated by HOLDB. To read data from channel $B, A 1$ is set high and $A 2$ is low. Since A0 is low during the first reading (A2 A1 A0 $=010$ ), data B0 are put to the output. Before the second RD, A0 switches high (A2 A1 A0 = 011) so that data from channel B1 are read, as shown in Table 1. However, reading data during the conversion or on a falling hold edge might cause a loss in performance.

Table 1. Address Control for $\overline{\mathrm{RD}}$ Functions

| A2 | A1 | A0 | CHANNEL TO BE READ |

| 1 | 1 | 1 | FIFO mode |

Figure 28. Timing of One Conversion Cycle

## Reading data ( $\overline{\mathrm{RD}}$ and $\overline{\mathrm{CS}}$ )

In general, the channel/data outputs are in tri-state. Both $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ must be low to enable these outputs. $\overline{\mathrm{RD}}$ and $\overline{\mathrm{CS}}$ must stay low together for at least 40 ns (see Figure 1, $\mathrm{t}_{\mathrm{DG}}$ ) before the output data are valid. RD must remain HIGH for at least 30ns (see Figure 1, $\mathrm{t}_{\mathrm{w} 5}$ ) before bringing it back low for a subsequent read command.
The new data are latched into its output register 16.5 clock cycles after the start of a conversion (next rising edge of clock after the falling edge of HOLDX). Even if the ADS8365 is forced to wait until the read process is finished ( $\overline{\mathrm{RD}}$ signal going high) before the new data are latched into its output register, the possibility still exists that the new data was latched to the output register just before the falling edge of RD. If a read process is initiated around 16.5 clock cycles after the conversion started, $\overline{\mathrm{RD}}$ and $\overline{\mathrm{CS}}$ should stay low for at least 50 ns (see Figure 1, $\mathrm{t}_{\text {w6 }}$ ) to get the new data stored to its register and switched to the output.
$\overline{\mathrm{CS}}$ being low tells the ADS8365 that the bus on the board is assigned to the ADS8365. If an ADC shares a bus with digital gates, there is a possibility that digital (high-frequency) noise will be coupled into the ADC. If the bus is just used by the ADS8365, $\overline{\mathrm{CS}}$ can be hardwired to ground. Reading data at the falling edge of one of the HOLDX signals might cause noise.

## BYTE

If there is only an 8 -bit bus available on a board, then BYTE can be set high (see Figure 29). In this case, the lower eight bits can be read at the output pins D15 to D8 or D7 to D0 at the first RD signal, and the higher bits after the second $\overline{\mathrm{RD}}$ signal. If the ADS8365 is used in the cycle or the FIFO mode, then the address and data valid information is added to the data (if ADD is high). In this case, the address will be read first, then the lower eight bits, and finally the higher eight bits. If BYTE is low, then the ADS8365 operates in the 16 -bit output mode. Here, data are read between pins DB15 and DB0. As long as ADD is low, with every $\overline{R D}$ impulse, data from a new channel are brought to the output. If ADD is high and the cycle or the FIFO mode is chosen; the first output word contains the address, while the second output word contains the 16-bit data.

Figure 29. Reading Data in Cycling Mode

## ADD Signal

In the cycle and the FIFO mode, it might be desirable to have address information with the 16 -bit output data. Therefore, ADD can be set high. In this case, two $\overline{\mathrm{RD}}$ signals (or three readings if the part is operated with BYTE being high) are necessary to read data of one channel, while the ADS8365 provides channel information on the first $\overline{\mathrm{RD}}$ signal (see Table 2 and なable 3).

## Soft Trigger Mode

Signals NAP, ADD, A0, A1, A2, RESET, HOLDA, HOLDB, and HOLDC are accessible through the data bus and control word. Bits NAP, ADD, A0, A1 and A2 are in an OR configuration with hardware pins. When software configuration is used, these pins must be connected to ground. Conversely, the RESET, HOLDA, HOLDB, and HOLDC bits are in a NAND configuration with the hardware pins. When software configuration is used, these pins must be connected to $B V_{D D}$.

If conversion timing between ADCs is not critical, Soft Trigger mode can allow all three HOLDX signals to be triggered simultaneously. This simultaneous triggering can be done by tying all three HOLDX pins high, and issuing a write ( $\overline{\mathrm{CS}}$ and $\overline{\mathrm{WR}}$ low) with the DB0, DB1, DB2, and DB7 bits low, and the reset bit (DB3) high. Writing a low to the reset bit (DB3) while the RESET pin is high forces a device reset, and all HOLDX signals that occur during that time are ignored.
The HOLDX signals start conversion automatically on the next clock cycle. The format of the two words that can be written to the ADS8365 are shown in table 4.
Bits DB5 and DB4 do not have corresponding hardware pins. Bit DB5 $=1$ enables Powerdown mode. Bit DB4 = 1 inverts the MSB of the output data, putting the output data in two's complement format. When DB4 is low, the data is in straight binary format.

Table 2. Overview of the Output Formats Depending on Mode When ADD $=0$

| ADD $=0$ | BYTE $=0$ |  | BYTE = 1 |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| A2 A1 A0 | 1st RD | 2nd RD | 1st RD | 2nd RD | 3rd RD |

## NAP AND POWERDOWN MODE CONTROL

In order to minimize power consumption when the ADS8365 is not in use, two low-power options are available. Nap mode minimizes power without shutting down the biasing circuitry and internal reference, allowing immediate recovery after it is disabled. It can be enabled by either the NAP pin going high, or setting DB6 in the data register high. Enabling Powerdown mode results in lower power consumption than Nap mode, but requires a short recovery period after disabling. It can only be enabled by setting DB5 in the data register high.

## GETTING DATA

## Flexible Output Modes: A0 A1, and A2.

The ADS8365 has three different output modes that are selected with A2, A1, and A0. The A2, A1 and A0 pins are held with a transparent latch that triggers on a falling edge of the RD pin negative-ANDed with the $\overline{\mathrm{CS}}$ pin (that is, if either $\overline{\mathrm{RD}}$ or $\overline{\mathrm{CS}}$ is low, the falling edge of the other will latch A0-2).
When (A2, A1, A0) $=000$ to 101, a particular channel can be directly addressed (see Table 1 and Figure 30). The channel address should be set at least 10 ns (see Figure 30, $\mathrm{t}_{\mathrm{Dg}}$ ) before the falling edge of RD and should not change as long as RD is low. In this standard address mode, ADD will be ignored, but should be connected to either ground or supply.
When $(A 2, A 1, A 0)=110$, the interface is running in a cycle mode (see Figure 29). Here, data 7 down to data 0 of channel A0 is read on the first $\overline{R D}$ signal, and data 15 down to data 8 on the second as BYTE is high. Then A 1 on the second $\overline{\mathrm{RD}}$, followed by BO ,

B1, C0, and finally, C1 before reading A0 again. Data from channel A0 are brought to the output first after a reset signal, or after powering up the device. The third mode is a FIFO mode that is addressed with (A2, A1, A0 $=111$ ). Data of the channel that is converted first is read first. So, if a particular channel pair is most interesting and is converted more frequently (for example, to get a history of a particular channel pair), then there are three output registers per channel available to store data.

If all the output registers are filled up with unread data and new data from an additional conversion must be latched in, then the oldest data is discarded. If a read process is going on ( $\overline{\mathrm{RD}}$ signal low) and new data must be stored, then the ADS8365 waits until the read process is finished ( $\overline{\mathrm{RD}}$ signal going high) before the new data gets latched into its output register. Again, with the ADD signal, it can be chosen whether the address should be added to the output data.
New data is always written into the next available register. At $\mathrm{t}_{0}$ (see Figure 31), the reset deletes all the existing data. At $t_{1}$, the new data of the channels A0 and A 1 are put into registers 0 and 1 . At $\mathrm{t}_{2}$, a dummy read ( $\overline{\mathrm{RD}}$ low) is performed to latch the address data correctly. At $\mathrm{t}_{3}$, the read process of channel A0 data is finished; therefore, these data are dumped and A1 data are shifted to register 0 . At $\mathrm{t}_{4}$, new data are available, this time from channels $\mathrm{BO}, \mathrm{B} 1, \mathrm{C} 0$, and C1. These data are written into the next available registers (registers 1, 2, 3, and 4).

Figure 30. Timing for Reading Data

Figure 31. Functionality Diagram of the FIFO Registers

On $\mathrm{t}_{5}$, the new read process of channel A1 data is finished. The new data of channel C0 and C1 at $\mathrm{t}_{6}$ are put on top (registers 4 and 5).
In Cycle mode and in FIFO mode, the ADS8365 offers the ability to add the address of the channel to the output data. Since there is only a 16 -bit bus available (or 8 -bit bus in the case BYTE is high), an additional $\overline{\mathrm{RD}}$ signal is necessary to get the information (see Table 2 and Table 3).
In FIFO mode, a dummy read signal ( $\overline{\mathrm{RD}}$ ) is required after a reset signal to set the address bits appropriately; otherwise, the first conversion will not be valid. This is only necessary in FIFO mode.

## The Output Code (DB15 ...DB0)

In the standard address mode (A2 A1 A0 = 000...101), the ADS8365 has a 16 -bit output word on pins DB15...DB0, if BYTE $=0$. If BYTE $=1$, then two RD impulses are necessary to first read the lower bits, and then the higher bits on either DB7...DB0 or DB15...DB8.
If the ADS8365 operates in Cycle or in FIFO mode and ADD is set high, then the address of the channel (A2A1A0) and a data valid (DV) bit are added to the data. If BYTE $=0$, then the data valid and the address of the channel is active during the first $\overline{\mathrm{RD}}$ impulse ( 100000000000 DV A2 A1 A0). During the
second $\overline{\mathrm{RD}}$, the 16 -bit data word can be read (DB15...DB0). If BYTE $=1$, then three $\overline{\text { RD }}$ impulses are needed. On the first $\overline{R D}$ impulse, data valid, the three address bits, and data bits DB3...DB0 (DV, A2, A1, A0, DB3, DB2, DB1, DB0) are read, followed by the eight lower bits of the 16 -bit data word (db7...db0), and finally the higher eight data bits (DB15...DB8). 100000000000 is added before the address in case BYTE $=0$, and DB3...DB0 is added after the address if BYTE $=1$. This provides the possibility to check if the counting of the $\overline{\mathrm{RD}}$ signals inside the ADS8365 are still tracking with the external interface (see Table 2 and Table 3).
The data valid bit is useful for the FIFO mode. Valid data can simply be read until the data valid bit equals 0 . The three address bits are listed in Table 55. If the FIFO is empty, 16 zeroes are loaded to the output.

Table 5. Address Bit in the Output Data

| DATA FROM ... | A2 | A1 | A0 |
| :--- | :---: | :---: | :---: |
| Channel A0 | 0 | 0 | 0 |
| Channel A1 | 0 | 0 | 1 |
| Channel B0 | 0 | 1 | 0 |
| Channel B1 | 0 | 1 | 1 |
| Channel C0 | 1 | 0 | 0 |
| Channel C1 | 1 | 0 | 1 |

## LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS8365 circuitry. This recommendation is particularly true if the CLK input is approaching the maximum throughput rate.
The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections, and digital inputs that occur just prior to latching the output of the analog comparator. Thus, driving any single conversion for an $n$-bit SAR converter, there are $n$ windows in which large external transient voltages can affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, or high-power devices. The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. Their error can change if the external event changes in time with respect to the CLK input.
With this information in mind, power to the ADS8365 should be clean and well-bypassed. A $0.1 \mu \mathrm{~F}$ ceramic bypass capacitor should be placed as close to the device as possible. In addition, a $1 \mu \mathrm{~F}$ to $10 \mu \mathrm{~F}$ capacitor is recommended. If needed, an even larger
capacitor and a $5 \Omega$ or $10 \Omega$ series resistor may be used to low-pass filter a noisy supply. On average, the ADS8365 draws very little current from an external reference because the reference voltage is internally buffered. A bypass capacitor of $0.1 \mu \mathrm{~F}$ and $10 \mu \mathrm{~F}$ are suggested when using the internal reference (tie pin 61 directly to pin 62).

## GROUNDING

The AGND pins should be connected to a clean ground point. In all cases, this point should be the analog ground. Avoid connections that are too close to the grounding point of a microcontroller or digital signal processor. If required, run a ground trace directly from the converter to the power-supply entry point. The ideal layout includes an analog ground plane dedicated to the converter and associated analog circuitry. Three signal ground pins (SGND) are the input signal grounds that are on the same potential as analog ground.

## APPLICATION INFORMATION

Different connection diagrams to DSPs or microcontrollers are shown in Figure 33 through Figure 39.

## Part Change Notification \# 20071210003

The ADS8365 device underwent a silicon change under Texas Instruments Part Change Notification (PCN) number 20071210003. Details of this change can be obtained from the Product Information Center at Texas Instruments or by contacting your local sales/distribution office. Devices with a date code of 81x and higher are covered by this PCN.

SBAS362C-AUGUST 2006-REVISED MARCH 2008

${ }^{(1)}$ The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but Tl does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.
${ }^{(2)}$ RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed $0.1 \%$ by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.
${ }^{(3)}$ MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
${ }^{(4)}$ There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
${ }^{(5)}$ Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
${ }^{(6)}$ Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
