

SGM2100

Seven-Channel, High Efficiency, DC-DC Power Management Unit

GENERAL DESCRIPTION

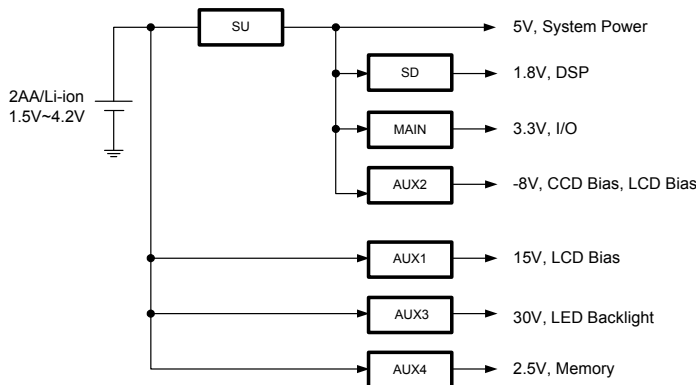

The SGM2100 is a single chip power management unit for a wide range of portable applications. It incorporates three synchronous switching regulators and four switching regulator controllers in a space saving thin QFN package. High efficiency, compact size and flexible configuration make SGM2100 the ideal power supply solution for two AA cells or single Li-ion battery powered equipments.

Synchronous switching regulators, SU, SD, & MAIN, provide the core powers for CPU, DSP and I/O. Switching regulator controllers, AUX1, AUX2, AUX3 and AUX4, coupled with external MOSFETs provide versatile auxiliary powers for image sensor, LCD panel bias, LED backlight, stepping motor, or memory module.

All channels operate at the same programmable constant switching frequency, ranging from 100kHz to 1MHz. Each channel, with built-in digital soft-start, can be individually selected, and programmed to the desired output voltage with two external resistors. Power OK, short-circuit flag and thermal protection features provide the system status and extra level of fault protection.

The SGM2100 is available in TQFN-7×7-48L package and is rated over the -40°C to +85°C temperature range.

TYPICAL APPLICATION IN DIGITAL CAMERAS

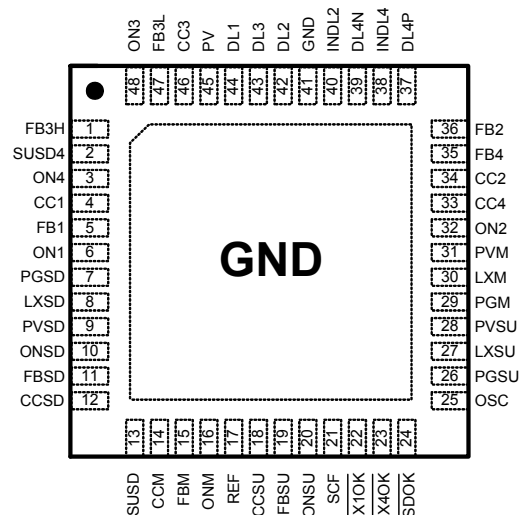

FEATURES

- 2A, Step-Up Synchronous Switching Regulator with 1.1V Start-Up Voltage, 90% Efficiency
- 1A, Step-Down Synchronous Switching Regulator, 90% Efficiency
- 1A, Pin Selectable Step-Up or Step-Down, Synchronous Switching Regulator, 90% Efficiency
- Step-Up Switching Regulator Controller, with Power OK Indicator
- Transformerless Inverting Switching Regulator Controller
- Constant Current Step-Up Switching Regulator Controller, LED Driver, with Output Open Protection
- Pin Selectable Step-Up or Step-Down Switching Regulator Controller, with Power OK Indicator
- Operates from 100kHz to 1MHz Switching Frequency
- Individual Enable, Digital Soft-Start and Overload Protection
- 1µA Quiescent Current in Shutdown Mode
- Available in TQFN-7×7-48L Package

APPLICATIONS

- Digital still Cameras, Camcorders
- Smart Mobile Phones, PDAs
- Portable GPS Equipments
- Handheld Multi-Media Equipments

PIN CONFIGURATION (TOP VIEW)

PACKAGE/ORDERING INFORMATION

ORDER NUMBER	PACKAGE DESCRIPTION	SPECIFIED TEMPERATURE RANGE	MARKING INFORMATION	PACKAGE OPTION
SGM2100YTQC48/TR	TQFN-7x7-48L	-40°C to +85°C	SGM2100YTQ48	Tape and Reel, 2500

ABSOLUTE MAXIMUM RATINGS

Storage Temperature Range..... -65°C to +125°C
 Junction Temperature.....150°C
 Operating Temperature Range..... -40°C to +85°C
 Lead Temperature (Soldering 10 sec)
 260°C
 ESD Susceptibility
 HBM..... 3000V
 MM.....200V

NOTE:

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

This integrated circuit can be damaged by ESD if you don't pay attention to ESD protection. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

SGMICRO reserves the right to make any change in circuit design, specification or other related things if necessary without notice at any time. Please contact SGMICRO sales office to get the latest datasheet.

PIN DESCRIPTION

PIN	NAME	FUNCTION
1	FB3H	Voltage Feedback Input of AUX3 Controller. Connect a resistive voltage-divider from the step-up converter output to FB3H to set the output voltage. The feedback threshold is 0.8V. This pin is high impedance in shutdown. FB3H provide conventional voltage.
2	SUSD4	Configures AUX4 as a Step-Up or a Step-Down. This function must be hardwired. On-the-fly changes are not allowed. Connected it to PV for Step-up mode, and connect it to GND for Step-down mode.
3	ON4	AUX4 Controller ON/OFF Input. Logic high = ON; however, turn-on is locked out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475kΩ pull-down resistance to GND.
4	CC1	AUX1 Controller Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload, and thermal limit.

PIN DESCRIPTION

PIN	NAME	FUNCTION
5	FB1	AUX1 Controller Feedback Input. The feedback threshold is 0.8V. This pin is high impedance in shutdown.
6	ON1	AUX1 Controller ON/OFF Input. Logic high = ON; however, turn-on is locked out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475kΩ pull-down resistance to GND.
7	PGSD	Power Ground. Connect all PGxx_ pins to GND with short wide traces as close to the IC as possible.
8	LXSD	Step-Down Converter Switching Node. Connect to the inductor of the step-down converter. LXSD is high impedance in shutdown.
9	PVSD	Step-Down Converter Supply Input. Bypass to GND with a 1μF ceramic capacitor. The efficiency of this channel is measured from this pin.
10	ONSD	Step-Down Converter ON/OFF Control Input. Logic high = ON; however, turn-on is locked out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475kΩ pull-down resistance to GND.
11	FBSD	Step-Down Converter Feedback Input. The feedback threshold is 0.8V. This pin is high impedance in shutdown.
12	CCSD	Step-Down Converter Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload and thermal limit.
13	SUSD	Configures the Main Converter as a Step-Up or a Step-Down. This function must be hardwired. On-the-fly changes are not allowed. With SUSD connected to PV, the main is configured as a step-up and PVM is the converter's output. With SUSD connected to GND, this channel is configured as a Step-Down, PVM is the Power Source Input Pin of Main Converter.
14	CCM	Main Converter Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload, and thermal limit.
15	FBM	Main Converter Feedback Input. The feedback threshold is 0.8V. This pin is high impedance in shutdown. The output voltage must not be set higher than the step-up output.
16	ONM	Main ON/OFF Input. Logic high = ON; however, turn-on is lock out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475kΩ pull-down resistance to GND.
17	REF	Reference Output. Bypass REF to GND with a 0.1μF or greater capacitor. The maximum allowed REF load is 200μA. REF is actively pulled to GND when the step-up is shutdown.
18	CCSU	Step-Up Converter Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload, and thermal limit.
19	FBSU	Step-Up Converter Feedback Input. The feedback threshold is 0.8V. This pin is high impedance in shutdown.
20	ONSU	Step-Up Converter ON/OFF Input. Logic high = ON; however, turn-on is lock out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475kΩ pull-down resistance to GND.

PIN DESCRIPTION

PIN	NAME	FUNCTION
21	SCF	Open-Drain, Active-Low, Short-Circuit Flag Output. SCF goes open when overload protection occurs and during startup. SCF can drive high-side PMOS switches connected to one or more outputs to completely disconnect the load when the channel turns off in response to a logic command or an overload.
22	$\overline{\text{AUX1OK}}$	Open-Drain, Active-Low, Power-OK Signal of AUX1. $\overline{\text{AUX1OK}}$ goes low when the AUX1 controller has successfully completed soft-start. $\overline{\text{AUX1OK}}$ goes high impedance in shutdown, overload, and thermal limit.
23	$\overline{\text{AUX4OK}}$	Open-Drain, Active-Low, Power-OK Signal of AUX4. $\overline{\text{AUX4OK}}$ goes low when the AUX4 controller has successfully completed soft-start. $\overline{\text{AUX4OK}}$ goes high impedance in shutdown, overload, and thermal limit.
24	$\overline{\text{SDOK}}$	Open-Drain, Active-Low, Power-OK Signal of Step-Down Converter. $\overline{\text{SDOK}}$ goes low when the step-down has successfully completed soft-start. $\overline{\text{SDOK}}$ goes high impedance in shutdown, overload and thermal limit.
25	OSC	Oscillator Control. Connect a timing capacitor from OSC to GND and a timing resistor from OSC to PVSU (or other DC voltage) to set the oscillator frequency between 100kHz and 1MHz. This pin is high impedance in shutdown.
26	PGSU	Power Ground. Connect all PGxx_ pins to GND with short wide traces as close to the IC as possible.
27	LXSU	Step-Up Converter Switching Node. Connect to the inductor of the step-up converter. LXSU is high impedance in shutdown.
28	PVSU	Power Output of the Step-Up Converter regulator. PVSU can also power other converter channels. Connect PVSU and PV together.
29	PGM	Power Ground. Connect all PGxx_ pins to GND with short wide traces as close to the IC as possible.
30	LXM	Main Converter Switching Node. Connect to the inductor of the main converter (can be configured as a step-up or a step-down by SUSD). LXM is high impedance in shutdown.
31	PVM	When SUSD = PVSU, the main converter channel is configured as a step-up and PVM is the main output. When SUSD = GND, main channel is configured as a step-down and PVM is the power input.
32	ON2	AUX2 Controller ON/OFF Input. Logic high = ON; however, turn-on is locked out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475k Ω pull-down resistance to GND.
33	CC4	AUX4 Controller Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload, and thermal limit.
34	CC2	AUX2 Controller Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload, and thermal limit.
35	FB4	AUX4 Controller Feedback Input. The feedback threshold is 0.8V. This pin is high impedance in shutdown.

PIN DESCRIPTION

PIN	NAME	FUNCTION
36	FB2	AUX2 Controller Feedback Input. This pin is high impedance in shutdown. Option1 AUX2 as a Step-Up: FB2 feedback threshold is 0.8V. Option2 AUX2 as an inverter: FB2 feedback threshold is 0.8V.
37	DL4P	AUX4 Controller Gate-Drive Output. DL4P drives between INDL4 and GND. The PMIC configures DL4P to drive a PMOS. DL4P is driven high in shutdown, overload and thermal limit.
38	INDL4	Voltage Input of AUX4 Controller Gate-Drive. The voltage at INDL4 sets the high gate-drive voltage. PMIC connect INDL4 to the external PMOS source terminal to ensure the PMOS is completely off when DL4P swing high.
39	DL4N	AUX4 controller Gate-Drive Output. DL4N drives between INDL4 and GND. The PMIC configures DL4N to drive an NMOS. DL4N is driven high in shutdown, overload and thermal limit.
40	INDL2	Voltage input of AUX2 Controller Gate-Drive. The voltage at INDL2 sets the high gate-drive voltage. PMIC connect INDL2 to the external PMOS source terminal to ensure the PMOS is completely off when DL2 swing high.
41	GND	Analog Ground. Connect all PGxx_ pins to GND with short wide traces as close to the IC as possible.
42	DL2	AUX2 Controller Gate-Drive Output. DL2 drives between INDL2 and GND. The Option1 configures DL2 to drive an NMOS in a Boost configuration. AUX2 is driven low in shutdown, overload and thermal limit.
		AUX2 Controller Gate-Drive Output. DL2 drives between INDL2 and GND. The PMIC configures DL2 to drive a PMOS in an Inverter configuration. AUX2 is driven low in shutdown, overload and thermal limit.
43	DL3	AUX3 Controller Gate-Drive Output. Connect to the gate of an NMOS. DL3 drives between PVSU and GND and supplies up to 500mA. This pin is actively driven to GND in shutdown, overload, and thermal limit.
44	DL1	AUX1 Controller Gate-Drive Output. Connect to the gate of an NMOS. DL1 drives between PVSU and GND and supplies up to 500mA. This pin is actively driven to GND in shutdown, overload, and thermal limit.
45	PV	IC Power Input. Connect PVSU and PV together.
46	CC3	AUX3 Controller Compensation Node. Connect a series resistor-capacitor from this pin to GND to compensate the control loop of the converter. This pin is actively driven to GND in shutdown, overload, and thermal limit.
47	FB3L	AUX3 Controller Current-Feedback Input. Connect a resistor from FB3L to GND to set LED current in LED boost-drive circuits. The feedback threshold is 0.2V. Connecting this pin to GND if just use the FB3H feedback. This pin is high impedance in shutdown.
48	ON3	AUX3 Controller ON/OFF Input. Logic high = ON; however, turn-on is locked out until 1024 OSC cycles after the step-up has reached regulation. This pin has an internal 475kΩ pull-down resistance to GND.

DETAILED DESCRIPTION

The SGM2100 includes the following blocks to build a multiple-output power management unit for portable equipments. It can accept inputs from a variety of sources including 1-cell Li+ batteries, 2-cell alkaline or NiMH batteries, and even systems designed to accept both battery types. The SGM2100 includes seven DC/DC converter channels to generate all required voltages:

- SU, step-up DC/DC switching regulator, with on-chip power FETs.
- MAIN, pin selectable step-up or step-down DC/DC switching regulator with on-chip power FETs.
- SD, step-down DC/DC switching regulator with on-chip power FETs.
- AUX1, DC/DC switching regulator controller for step-up and flyback converters.
- AUX2, DC/DC switching regulator controller for step-up and inverting DC/DC application.
- AUX3, DC/DC switching regulator controller for white LED as well as conventional step-up applications; includes open LED overvoltage protection.
- AUX4, pin selectable step-up or step-down DC/DC switching regulator controller.

SU, Step-Up DC/DC Switching Regulator

The step-up DC/DC switching converter typically is used to generate a 5V output voltage from a 1.5V to 4.5V battery input, but any output voltage from V_{IN} to 5V can be set. An internal NFET switch and external synchronous rectifier allow conversion efficiencies as high as 90%. For heavy loading case, the converter operates in a low-noise PWM mode with constant frequency. Switching harmonics generated by fixed-frequency operation are consistent and easily filtered. Efficiency is enhanced under light (<75mA TYP) loading by a Power saving Mode that switches the step-up only as needed to service the load. In this mode, the maximum inductor current is 200mA for each pulse.

MAIN, Step-Up or Step-Down DC/DC Switching Regulator

The main converter can be configured as a step-up (Figure 2) or a step-down converter (Figure 1) under the control of SUSD pin. The main DC/DC converter is typically used to generate 3.3V, but any voltage from 2.7V to 5V can be set; however, the main output must not be set higher than the step-up output (PVSU).

An internal MOSFET switch and synchronous rectifier allow conversion efficiencies as high as 90%. Under moderate to heavy loading, the converter operates in a low-noise PWM mode with constant frequency. Switching harmonics generated by fixed-frequency operation are consistent and easily filtered. Efficiency is enhanced under light loading (<200mA typical for step-up mode, <150mA typical for step-down mode) by assuming a Power Saving Mode during which the converter switches only as needed to service the load.

Step-down operation can be direct from a Li+ cell if the minimum input voltage exceeds the desired output by approximately 200mV. Note that if the main DC/DC, operating as a step-down, operates in dropout, the overload protection circuit senses an out-of-regulation condition and turns off all channels.

Li+ Battery to 3.3V Boost-Buck Operation

When generating 3.3V from an Li+ cell, boost-buck operation may be needed, so a regulated output can be maintained for input voltages above and below 3.3V. In this case, it may be best to configure the main converter as a step-down (SUSD = GND) and to connect its input, PVM, to the step-up output (PVSU), set to a voltage at or above 4.2V (Figures 1 and 3). The compound efficiency with this connection is typically up to 90%. This connection is also suitable for designs that must operate from both 1-cell Li+ and 2 AA cells.

Note that the step-up output supplies both the step-up load and the main step-down input current when the main is powered from the step-up. The main input current reduces the available step-up output current for other loads.

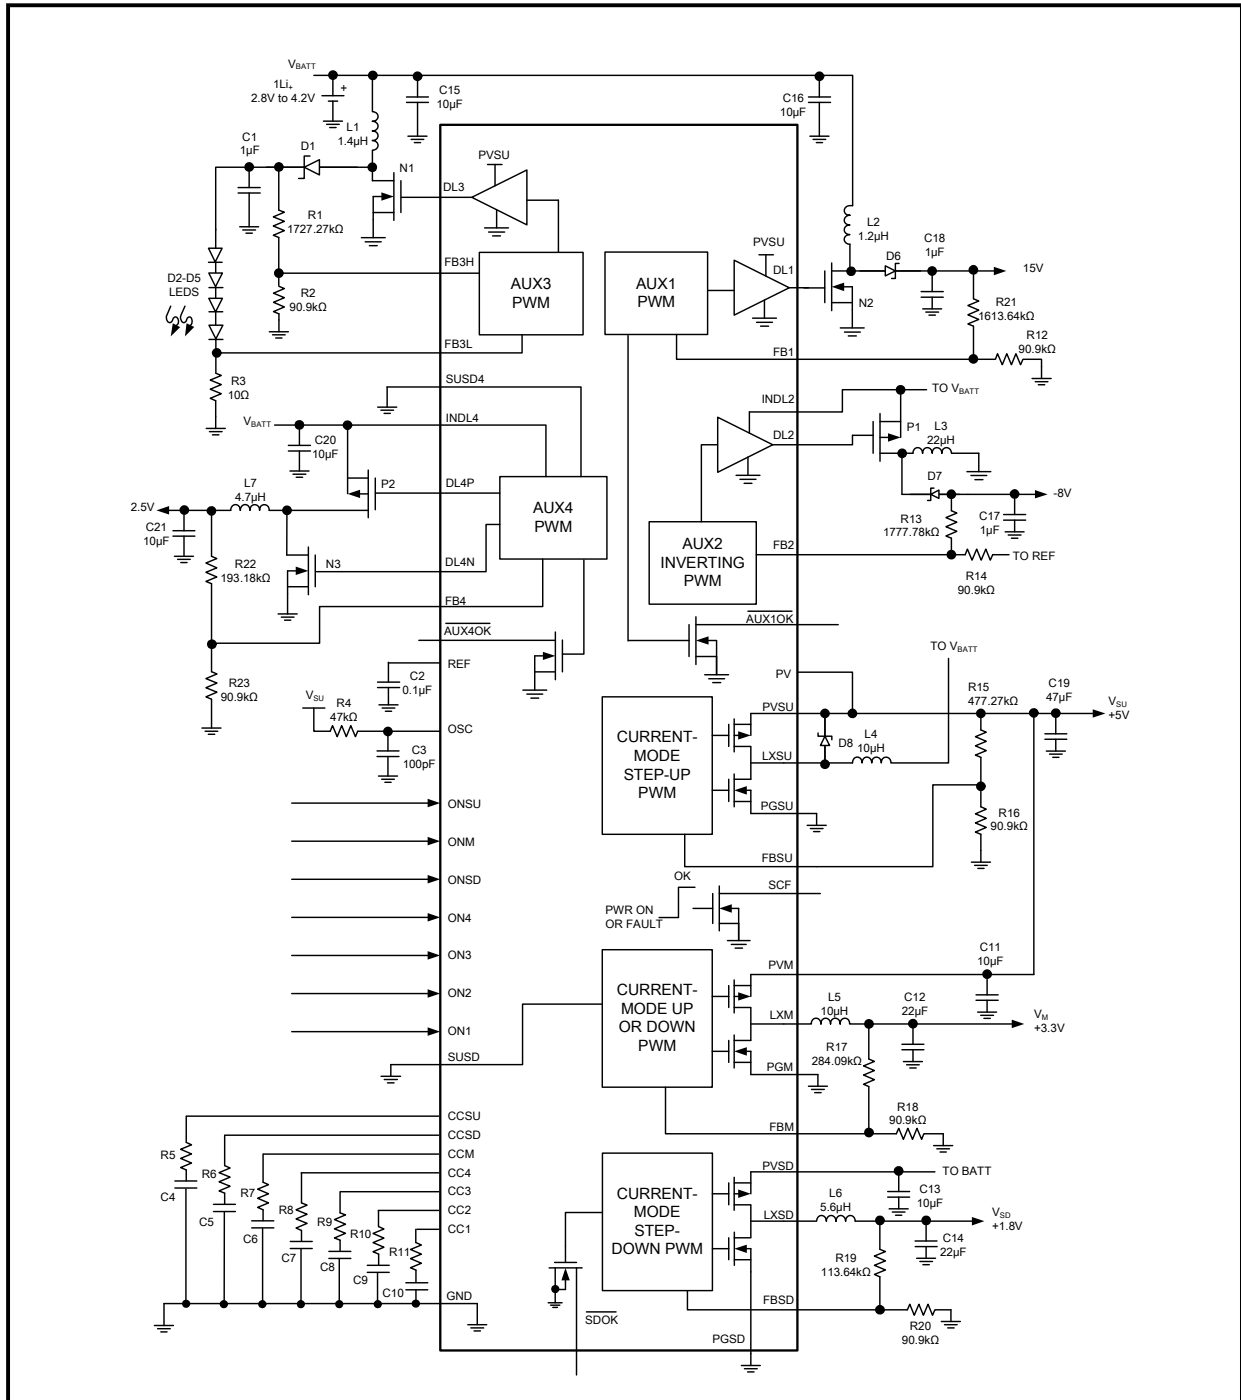

Figure 1. Typical 1-Cell Li+ Powered System (3.3V logic is stepped down from +5V or Battery, and 1.8V core is stepped down directly from the battery. Alternate connections are shown in the following figures.)

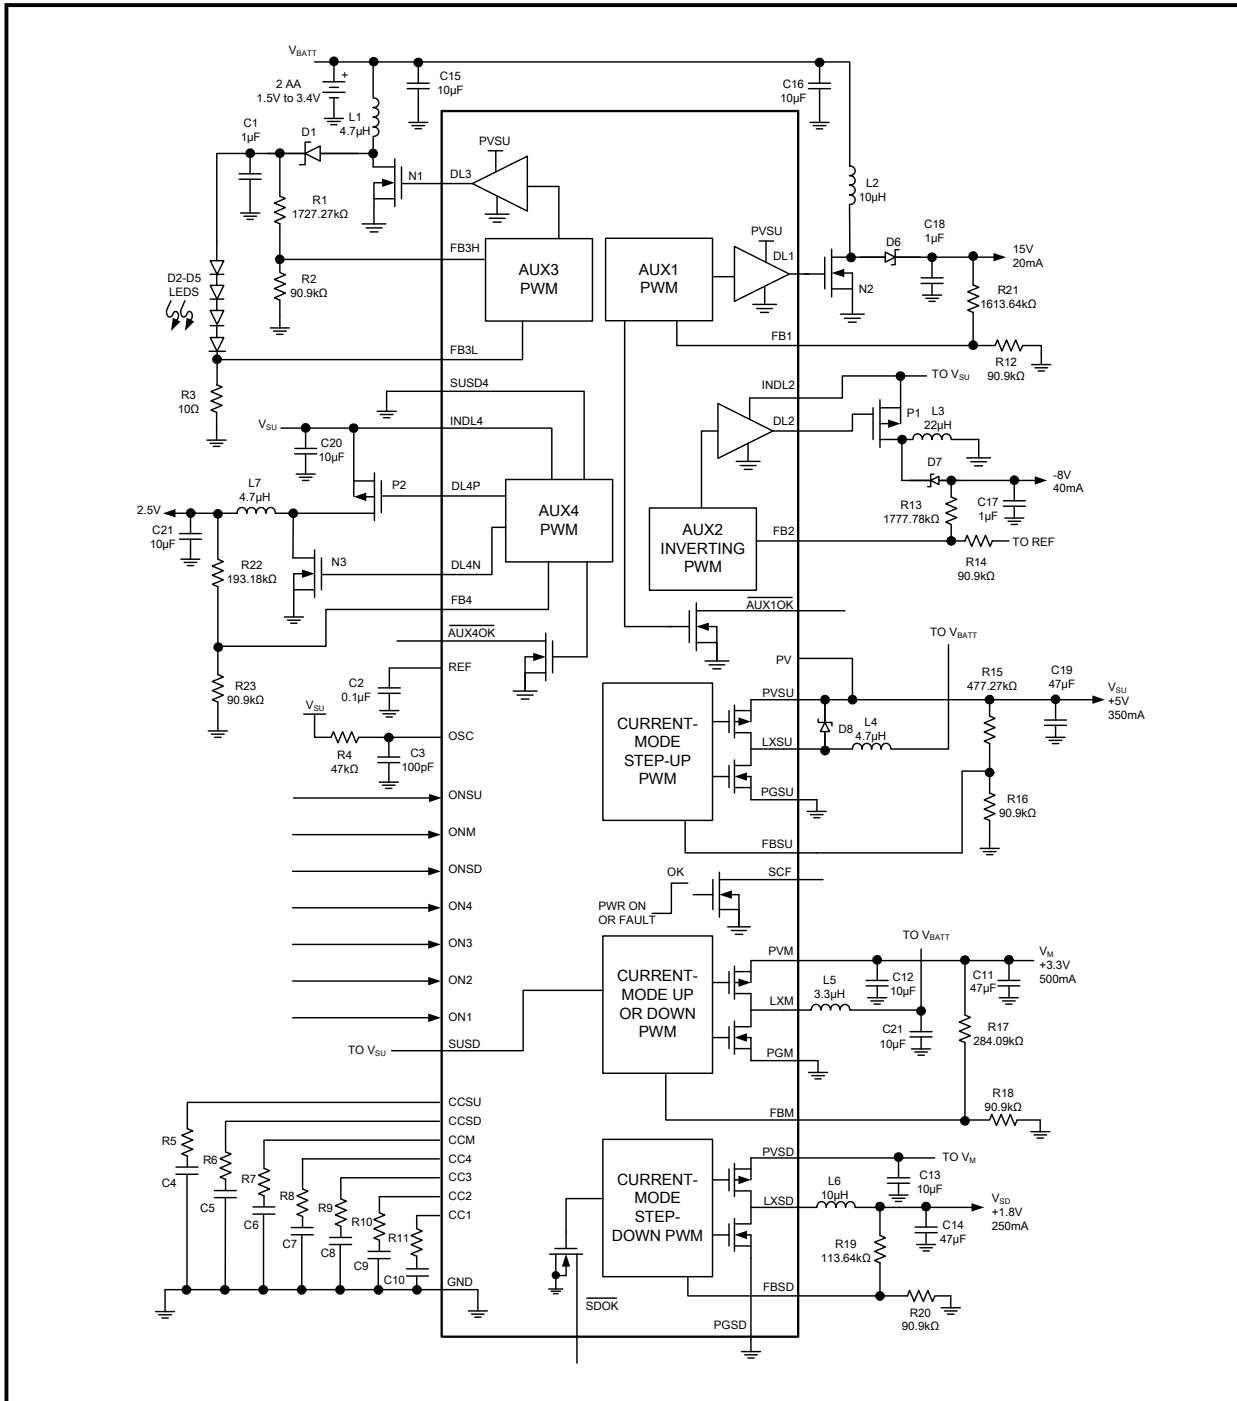

Figure 2. Typical 2-Cell AA-Powered System (3.3V is boosted from the battery and 1.8V is stepped down from V_M (3.3V).)

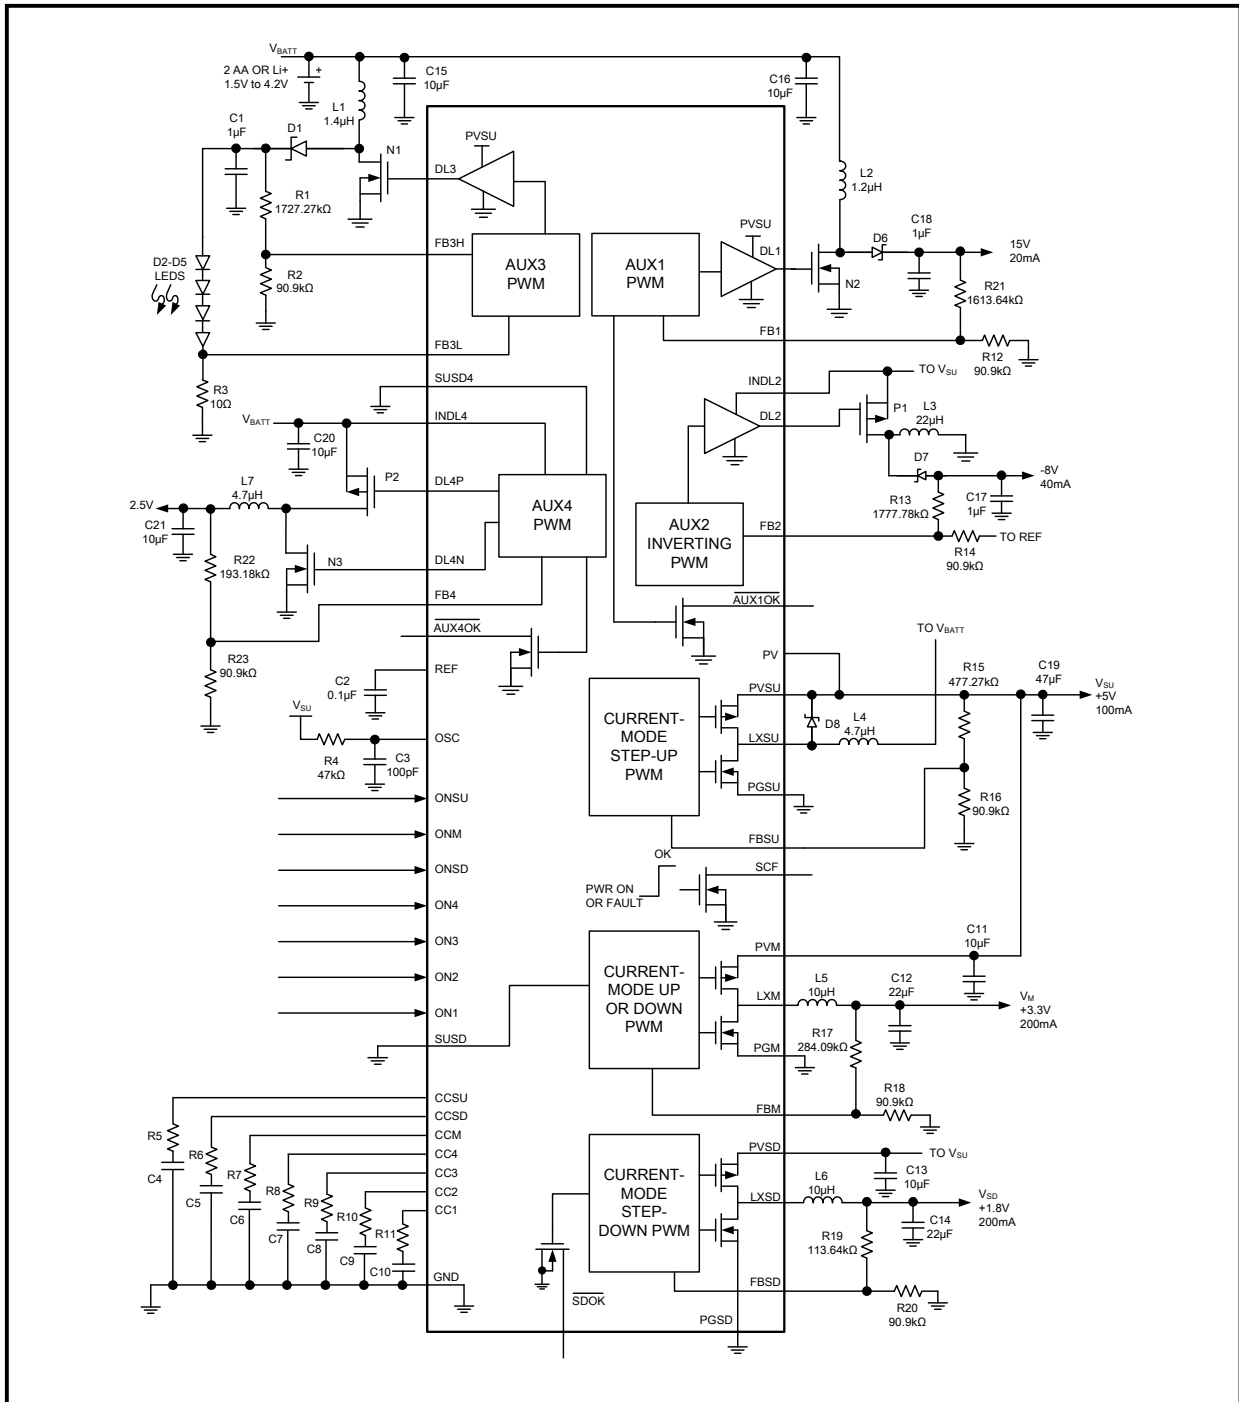

Figure 3. Li+ or Multi-battery Input (This power supply accepts inputs from 1.5V to 4.2V, so it can operate from either 2 AA cells or 1 Li+ cell. The 3.3V logic supply and the 1.8V core supply are both stepped down from 5V for true boost-buck operation.)

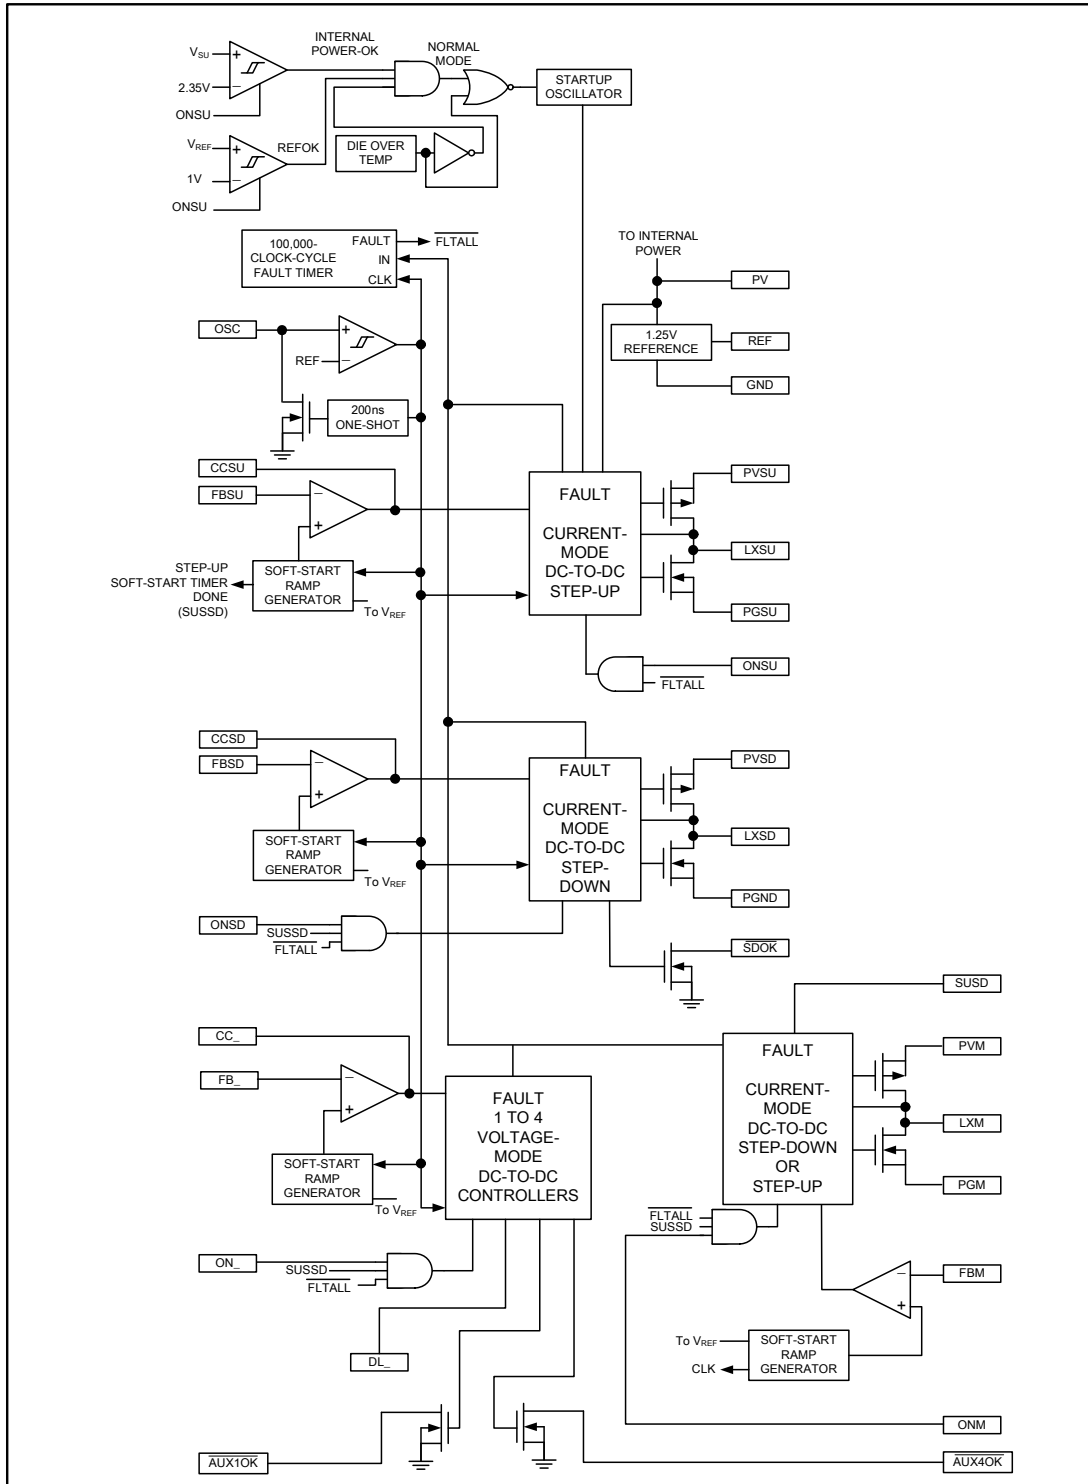

Figure 4. SGM2100 Functional Diagram

2 AA to 3.3V Operation

In designs that operate only from 2 AA cells, the main DC/DC can be configured as a boost converter (SUSD = PVSU) to maximize the 3.3V efficiency (Figure 2).

SD, Step-Down DC/DC Switching Regulator

The step-down DC/DC is optimized for generating low output voltages (down to 0.8V) at high efficiency. It runs from the power source from PVSD pin. PVSD pin can be connected directly to the battery if sufficient headroom exists to avoid dropout; otherwise, PVSD can be powered from the output of another converter. This Buck can also operate with the step-up (main converter in step-up mode) for boost- buck operation.

For heavy loading, the converter operates in a low-noise PWM mode with constant frequency and modulated pulse width. Efficiency is enhanced under light (<75mA TYP) loading by assuming a Power saving Mode during which the step-down switches only as needed to service the load. In this mode, the maximum inductor current is 150mA for each pulse. The step-down DC/DC is inactive until the step-up DC/DC is in regulation.

The step-down also features an open-drain $\overline{\text{SDOK}}$ output that goes low when the step-down output is in regulation. $\overline{\text{SDOK}}$ can be used to drive an external MOSFET switch that gates 3.3V power to the processor after the core voltage is in regulation. This connection is shown in Figure 15.

AUX1, AUX2, AUX3, AUX4 DC/DC Controllers

The four auxiliary controllers operate as fixed- frequency voltage-mode PWM controllers. They do not have internal MOSFETs, so output power is determined by external components. The controllers regulate output voltage by modulating the pulse width of the DL_ driver.

On the SGM2100, AUX1 and AUX2 are boost/flyback PWM controllers. AUX3 is a boost/flyback controller that can be connected to regulate output voltage and/or current (for white-LED drive). AUX4 can be configured to Buck or Boost controller by SUSD4 pin, the output power is dependent on external MOSFETs.

Figure 5 shows a functional diagram of an AUX1/AUX2 boost controller. A sawtooth oscillator signal at OSC governs timing. At the start of each cycle, DL1/DL2 goes high, turning on the external NFET switch. The switch then turns off when the internally level-shifted sawtooth rises above the voltage at CC1/CC2 pin or when the maximum duty cycle is exceeded. The switch remains off until the start of the next cycle. A transconductance error amplifier forms an integrator at CC1/CC2 to maintain high DC loop gain and accuracy.

The auxiliary controllers do not start until 1024 OSC cycles after the step-up DC/DC output is in regulation. If the auxiliary controller remains faulted for 100,000 OSC cycles (200ms at 500kHz), then all SGM2100 channels latch off.

Figure 11, 12, 13 and 14 are several circuit schemes in system design.

Maximum Duty Cycle

The AUX PWM controllers have a guaranteed maximum duty cycle of 80%: all controllers can achieve at least 80% and typically reach 85%. In boost designs that employ continuous current, the maximum duty cycle limits the boost ratio so:

$$1 - V_{IN} / V_{OUT} \leq 80\%$$

With discontinuous inductor current, no such limit exists for the input/output ratio since the inductor has time to fully discharge before the next cycle begins.

AUX1, Step-Up DC/DC Controller

AUX1 can be used for conventional DC/DC boost and flyback designs (Figures 8 and 9). Its output (DL1) is designed to drive an N-Channel MOSFET. Its feedback (FB1) threshold is 0.8V.

AUX2, Step-Up DC/DC controller

In the SGM2100, AUX2 can be used as boost or inverting DC/DC controller, in inverting DC/DC application, AUX2 generates a regulated negative output voltage, typically for CCD and LCD bias. This is useful in height-limited designs where transformers may not be desired.

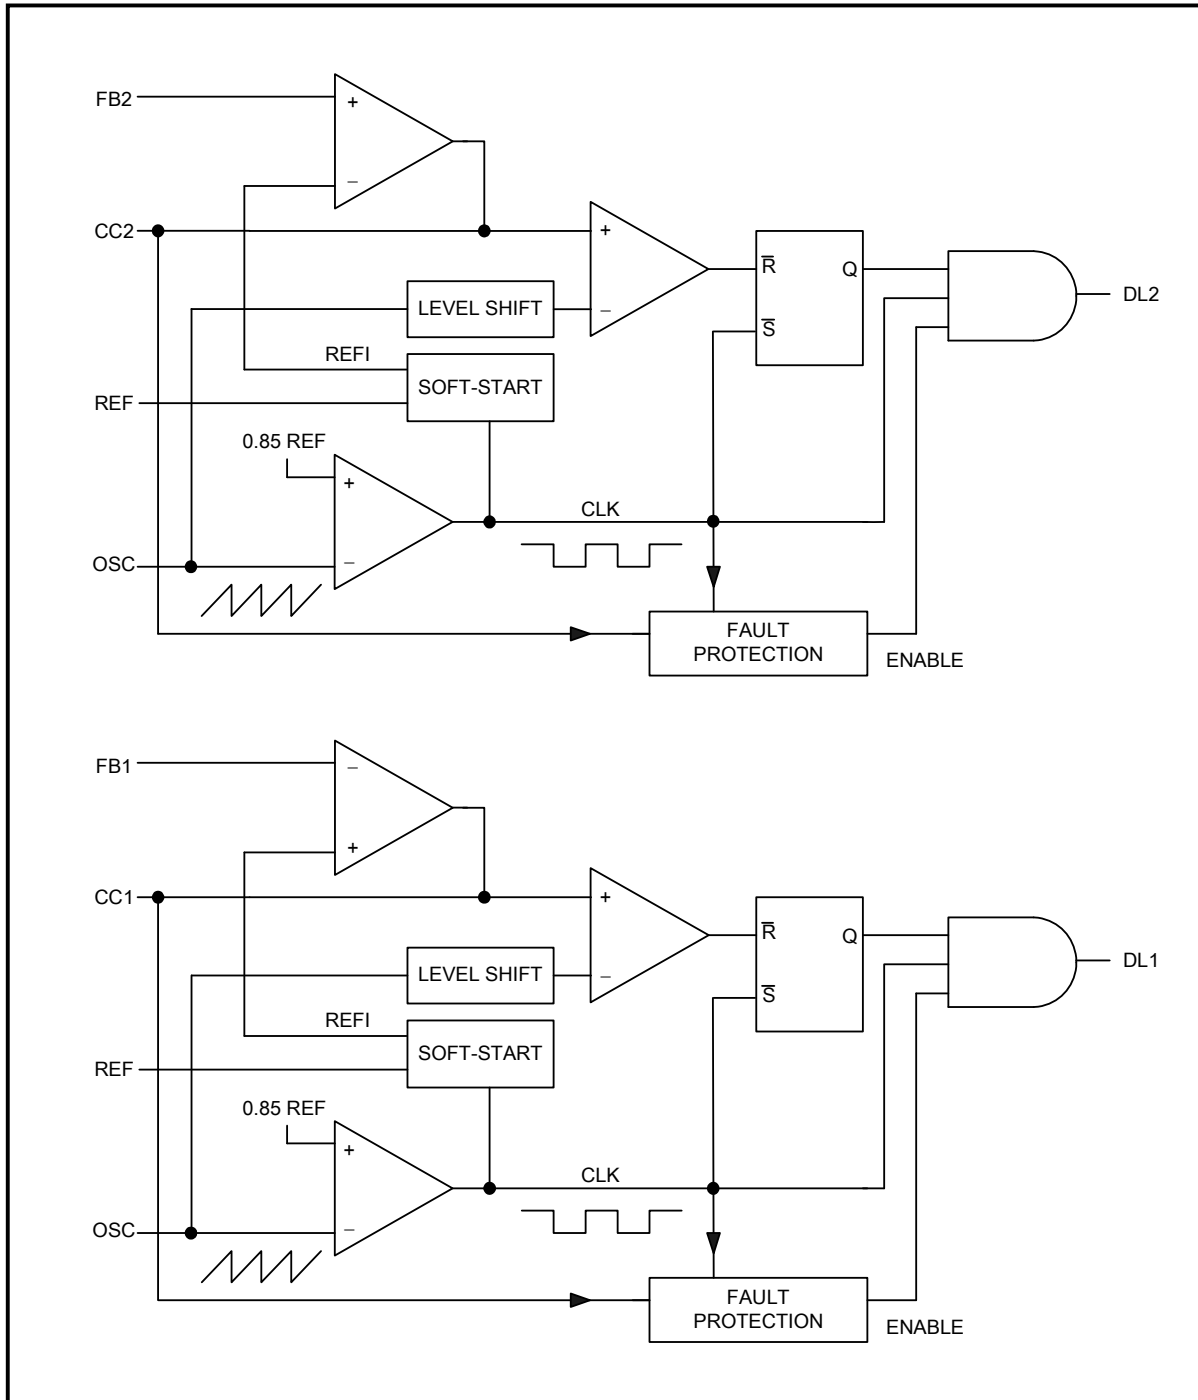

Figure 5. AUX1 and AUX2 Controller Functional Diagram

Figure 6. Oscillator Function Diagram

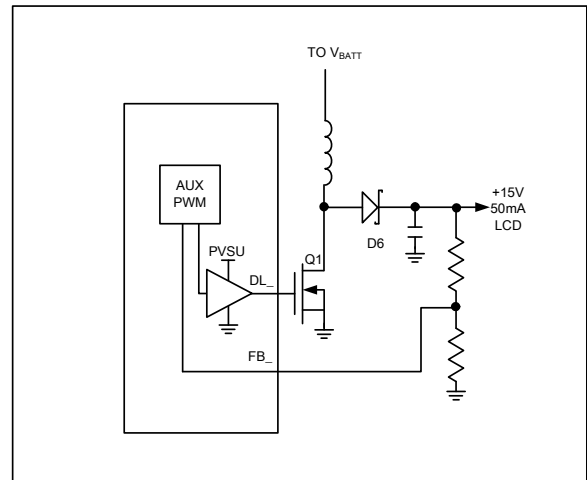

Figure 8. Boost DC/DC

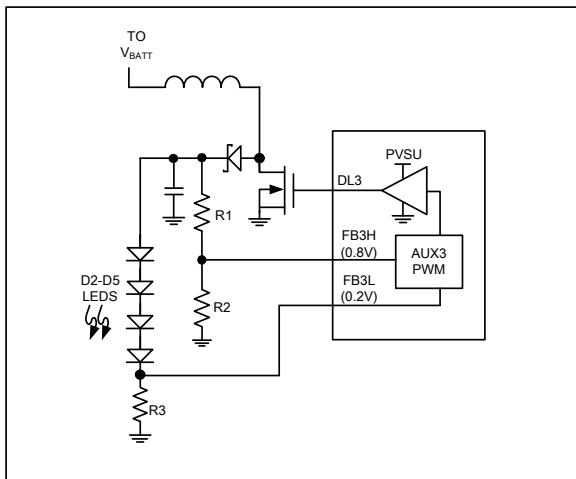

Figure 7. White LED drive with open LED overvoltage protection is provided by the additional voltage feedback input to FB3H

The AUX2 MOSFET driver (DL2) is designed to drive P-Channel MOSFETs. INDL2 biases the driver so V_{INDL2} is the high output level of DL2. INDL2 should be connected to the P-Channel MOSFET source to ensure the MOSFET turns completely off when DL2 is high.

AUX3, Step-Up DC/DC Controller or LED Driver

The AUX3 step-up DC/DC controller has two feedback inputs, FB3L and FB3H, with feedback thresholds of 0.2V (FB3L) and 0.8V (FB3H). If used as a conventional voltage-output step-up, FB3L is grounded and FB3H is used as the feedback input. In such case, AUX3 behaves exactly like AUX1.

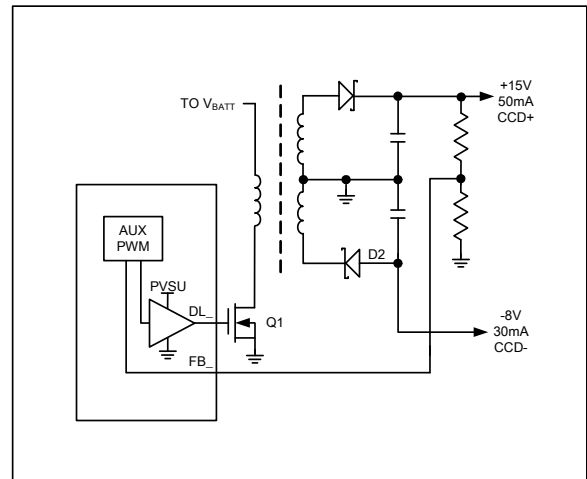

Figure 9. +15V and -8V CCD Bias with Transformer

If AUX3 is used as a switch-mode boost current source for white LEDs, FB3L provides current-sensing feedback, while FB3H provides (optional) open-LED overvoltage protection (Figure 7). In this application, the member of white-LED can be 3, 4 or more; it's dependent on the power Source Voltage.

AUX4, Step-Up or Step-Down DC/DC Controller

AUX4 can be configured to Sync. Buck controller, by connecting SUS4 pin to GND, Figure10 is Sync. Buck DC/DC. This Sync. Buck can provide big current for heavy loading, customer can select different external MOSFETs to provide different output current.

Status Outputs ($\overline{\text{SDOK}}$, $\overline{\text{AUX1OK}}$, $\overline{\text{AUX4OK}}$, SCF)

The SGM2100 includes four versatile status outputs that can provide information to the system. All are open-drain outputs and can directly drive MOSFET switches to facilitate sequencing, disconnect loads during overloads, or perform other hardware-based functions.

$\overline{\text{SDOK}}$ pulls low when the step-down has successfully completed soft-start. $\overline{\text{SDOK}}$ goes high impedance in shutdown, overload, and thermal limit. A typical use for $\overline{\text{SDOK}}$ is to drive a P-Channel MOSFET that connects 3.3V power to the CPU I/O after the CPU core is powered up (Figure 15), thus providing safe sequencing in hardware without system intervention.

$\overline{\text{AUX1OK}}$ pulls low when the AUX1 controller has successfully completed soft-start. $\overline{\text{AUX1OK}}$ goes high impedance in shutdown, overload, and thermal limit. A typical use for $\overline{\text{AUX1OK}}$ is to drive a P-Channel MOSFET that connects 5V power to the CCD after the 15V CCD bias (generated by AUX1) is powered up (Figure 16). $\overline{\text{AUX4OK}}$ is Power OK signal of AUX4 controller.

SCF goes high (high impedance, open drain) when overload protection occurs. Under normal operation, SCF pulls low. SCF can drive a high-side P-Channel MOSFET switch that can disconnect a load during power-up or when a channel turns off in response to a logic command or an overload. Several connections are possible for SCF. One is shown in Figure 17 where SCF provides load disconnect for the step-up on fault and power-up.

Soft-Start

The SGM2100 channels feature a soft-start function that limits inrush current and prevents excessive battery loading at startup by ramping the output voltage of each channel up to the regulation voltage. This is accomplished by ramping the internal reference inputs to each channel error amplifier from 0V to the 0.8V reference voltage over a period of 4096 oscillator cycles (16ms at 500kHz) when initial power is applied or when a channel is enabled.

The step-down soft-start ramp takes half the time (2048 clock cycles) of the other channel ramps. This allows the step-down and main outputs to track each other and rise at nearly the same dV/dt rate on power-up. Once the step-down output reaches its regulation point (1.5V or 1.8V TYP), the main output (3.3V TYP) continues to rise at the same ramp rate. See the Typical Performance Characteristics Main and Step-Down Startup Waveforms graphs.

Soft-start is not included in the SU channel to avoid limiting startup capability with loading.

Fault Protection

The SGM2100 has robust fault and overload protection. After power-up, the device is set to detect an out-of-regulation state that could be caused by an overload or short. If any DC/DC converter channel (step-up, main, step-down, or any of the auxiliary controllers) remains faulted for 100,000 clock cycles (200ms at 500kHz), then all outputs latch off until the SU channel is reinitialized by the ONSU pin or by cycling the input power. The fault detection circuitry for any channel is disabled during its initial turn-on soft-start sequence.

An exception to the standard fault behavior is that there is no 100,000 clock cycle delay in entering the fault state if the step-up output (PVSU) is dragged below its 2.5V UVLO threshold or is shorted. In this case, the step-up UVLO immediately triggers and shuts down all channels. The step-up then continues to attempt starting. If the step-up output short remains, these attempts cannot succeed since PVSU remains near ground.

If a soft-short or overload remains on PVSU, the startup oscillator switches the internal N-Channel MOSFET, but fault is retriggered if regulation is not achieved by the end of the soft-start interval. If PVSU is dragged below the input, the overload is supplied by the body diode of the internal synchronous rectifier, or by a Schottky diode connected from the battery to PVSU. If desired, this overload current can be interrupted by a P-Channel MOSFET controlled by SCF, as shown in Figure 17.

Reference

The SGM2100 has a precise 1.25V reference. Connect a 0.1µF ceramic bypass capacitor from REF to GND within 0.2in (5mm) of the REF pin. REF can source up to 200µA and is enabled whenever ONSU is high and PVSU is above 2.5V. If the 200µA REF load limit must be exceeded, buffer REF with an external op amp.

Oscillator

All DC/DC converter channels employ fixed-frequency PWM operation. The operating frequency is set by an RC network at the OSC pin. The range of usable settings is 100kHz to 1MHz. Figure 6 is the function diagram of oscillator.

The oscillator uses a comparator, a 200ns one-shot, and an internal NFET switch in conjunction with an external timing resistor and capacitor (Figure 6). When the switch is open, the capacitor voltage exponentially approaches the step-up output voltage from zero with a time constant given by the product of R_{OSC} and C_{OSC} . The comparator output switches high when the capacitor voltage reaches V_{REF} (1.25V). In turn, the one-shot activates the internal MOSFET switch to discharge the capacitor for 200ns, and the cycle repeats. The oscillation frequency changes as the main output voltage ramps upward following startup. The oscillation frequency is then constant once the main output is in regulation.

Shutdown

The step-up converter is activated with a high input at ONSU. The main converter (step-up or step-down) is activated by a high input on ONM. The step-down and auxiliary DC/DC converters 1, 2, 3 and 4 activate with high inputs at ONSD, ON1, ON2, ON3 and ON4 respectively. The step-down, main, and AUX_ converters cannot be activated until PVSU is in regulation. For automatic startup, connect ON_ to PVSU or a logic level greater than 1.6V.

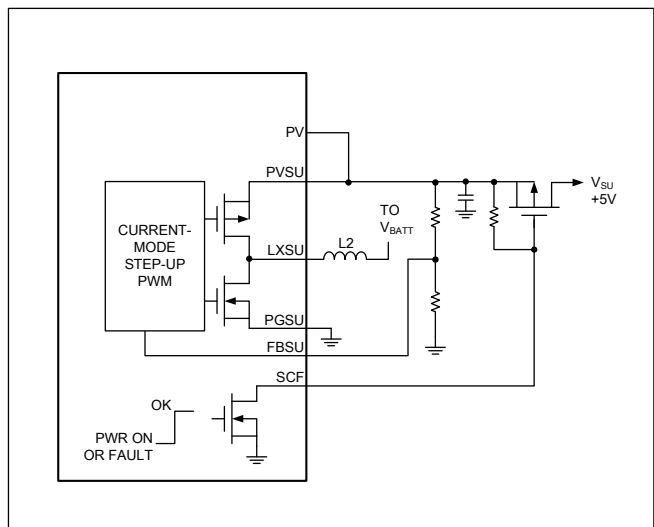

Figure 17. SCF Drives PFET Load Switch on 5V to Disconnect Load on Fault and Allow Full-Load Startup

Low-Voltage Startup Oscillator

The SGM2100 internal control and reference voltage circuitry receive power from PVSU and do not function when PVSU is less than 2.5V. To ensure low voltage startup, the step-up employs a low-voltage startup oscillator that activates at 1.2V if a Schottky rectifier is connected from V_{BATT} to PVSU (1.1V with no Schottky rectifier). The startup oscillator drives the internal N-Channel MOSFET at LXSU until PVSU reaches 2.5V, at which point voltage control is passed to the current-mode PWM circuitry.

Once in regulation, the SGM2100 operates with inputs as low as 1.1V since internal power for the IC is supplied by PVSU. At low input voltages, the step-up may have difficulty starting into heavy loads; however, this can be remedied by connecting an external P-Channel load switch driven by SCF so the load is not connected until the PVSU is in regulation (Figure 17).

DESIGN GUIDE

Setting the Switching Frequency

Choose a switching frequency to optimize external component size or circuit efficiency for the particular application. Typically, switching frequencies between 400kHz and 500kHz offer a good balance between component size and circuit efficiency—higher frequencies generally allow smaller components, and lower frequencies give better conversion efficiency. The switching frequency is set with an external timing resistor (R_{OSC}) and capacitor (C_{OSC}). At the beginning of a cycle, the timing capacitor charges through the resistor until it reaches V_{REF} . The charge time, t_1 , is as follows:

$$t_1 = -R_{OSC} \times (C_{OSC} + C_{par}) \times \ln [1 - (1.25 / V_{PVSU})]$$

where C_{par} (15pF TYP) is the parasitic capacitance at the OSC pin due to internal ESD protection structure and the die-to-package capacitance.

The internal comparator that compares the capacitor C_{OSC} voltage to the reference has a delay t_d of 50ns (TYP). The capacitor voltage then decays to zero over time, $t_2 = 200$ ns. The oscillator frequency is as follows:

$$f_{OSC} = 1 / (t_1 + t_d + t_2)$$

f_{OSC} can be set from 100kHz to 1MHz. Choose C_{OSC} between 22pF and 470pF. Determine R_{OSC} :

$$R_{OSC} = (200\text{ns} + 50\text{ns} - 1 / f_{OSC}) / [(C_{OSC} + C_{par}) \ln [1 - 1.25 / V_{PVSU}]]$$

See the Typical Performance Characteristics for f_{OSC} vs. R_{OSC} using different values of C_{OSC} .

Setting Output Voltages

All SGM2100 output voltages are resistor set. The FB_{-} threshold is 0.8V for all channels except for $FB3L$ (0.2V). When setting the voltage for any channel, connect a resistive voltage-divider from the channel output to the corresponding FB_{-} input and then to GND. The FB_{-} input bias current is less than 100nA, so choose the bottom-side (FB_{-} -to-GND) resistor to be 100k Ω or less. Then calculate the top-side (output-to- FB_{-}) resistor:

$$R_{TOP} = R_{BOTTOM} [(V_{OUT} / 0.8) - 1]$$

When using AUX3 to drive white LEDs (Figure 7), select the LED current-setting resistor R_3 (Figure 7) using the following formula:

$$R_3 = 0.2V / I_{LED}$$

The $FB2$ threshold is 0.8V, to set the AUX2 negative output voltage, connect a resistive voltage-divider from the negative output to the $FB2$ input, and then to REF. The $FB2$ input bias current is less than 100nA, so choose the REF-side ($FB2$ -to-REF) resistor (R_{REF}) to be 100k Ω or less. Then calculate the top-side (output-to- $FB2$) resistor:

$$R_{TOP} = \frac{0.8 + |V_{OUT}|}{0.45} \times R_{REF}$$

General Filter Capacitor Selection

The input capacitor in a DC/DC converter reduces current peaks drawn from the battery or other input power source and reduces switching noise in the controller. The impedance of the input capacitor at the switching frequency should be less than that of the input source so high-frequency switching currents do not pass through the input source. One 4.7 μ F to 10.0 μ F and one 0.01 μ F ceramic capacitors are recommended to be used as decoupling capacitors.

The output capacitor keeps output ripple small and ensures control-loop stability. The output capacitor must also have low impedance at the switching frequency. Ceramic, polymer, and tantalum capacitors are suitable, with ceramic exhibiting the lowest ESR and high-frequency impedance.

Output ripple with a ceramic output capacitor is approximately as follows:

$$V_{RIPPLE} = I_{L(PEAK)} [1 / (2\pi \times f_{OSC} \times C_{OUT})]$$

If the capacitor has significant ESR, the output ripple component due to capacitor ESR is as follows:

$$V_{RIPPLE(ESR)} = I_{L(PEAK)} \times ESR$$

Output capacitor specifics are also discussed in each converter's Compensation section.

Step-Up Component Selection

This section describes component selection for the step-up, as well as for the main, if $SUSD = PV$.

The external components required for the step-up are an inductor, an input and output filter capacitor, and a compensation RC.

The inductor is typically selected to operate with continuous current for best efficiency. An exception might be if the step-up ratio, (V_{OUT} / V_{IN}) , is greater than $1 / (1 - D_{MAX})$, where D_{MAX} is the maximum PWM duty factor of 80%.

When using the step-up channel to boost from a low input voltage, loaded startup is aided by connecting a Schottky diode from the battery to PVSU.

Step-Up Inductor

In most step-up designs, a reasonable inductor value (L_{IDEAL}) can be derived from the following equation, which sets continuous peak-to-peak inductor current at 1/2 the DC inductor current:

$$L_{IDEAL} = [2V_{IN(MAX)} \times D(1 - D)] / (I_{OUT} \times f_{OSC})$$

where D is the duty factor given by:

$$D = 1 - (V_{IN} / V_{OUT})$$

Given L_{IDEAL} , the consistent peak-to-peak inductor current is $0.5 I_{OUT} / (1 - D)$. The peak inductor current, $I_{IND(PK)} = I_{OUT} / (1 - D)$.

Inductance values smaller than L_{IDEAL} can be used to reduce inductor size; however, if much smaller values are used, inductor current rises and a larger output capacitance may be required to suppress output ripple.

Step-Up Compensation

The inductor and output capacitor are usually chosen first in consideration of performance, size, and cost. The compensation resistor and capacitor are then chosen to optimize control-loop stability. In some cases, it may help to re-adjust the inductor or output-capacitor value to get optimum results. For typical designs, the component values in the circuit of Figure 1 yield good results.

The step-up converter employs current-mode control, thereby simplifying the control-loop compensation. When the converter operates with continuous inductor current (typically the case), a right-half-plane zero appears in the loop-gain frequency response. To ensure stability, the control-loop gain should cross over (drop below unity gain) at a frequency (f_C) much less than that of the right-half-plane zero.

The relevant characteristics for step-up channel compensation are as follows:

- Transconductance (from FB to CC), g_{mEA} (135 μ S)
- Current-sense amplifier transresistance, R_{CS} (0.3V/A)
- Feedback regulation voltage, V_{FB} (0.8V)
- Step-up output voltage, V_{SU} , in V
- Output load equivalent resistance, R_{LOAD} , in $\Omega = V_{OUT} / I_{LOAD}$

The key steps for step-up compensation are as follows:
1) Place f_C sufficiently below the right-half-plane zero (RHPZ) and calculate C_C .

2) Select R_C based on the allowed load-step transient. R_C sets a voltage delta on the C_C pin that corresponds to load-current step.

3) Calculate the output-filter capacitor (C_{OUT}) required to allow the R_C and C_C selected.

4) Determine if C_P is required.(if calculated to be >10pF) For continuous conduction, the right-half-plane zero frequency (f_{RHPZ}) is given by the following:

$$f_{RHPZ} = V_{OUT}(1 - D)^2 / (2\pi \times L \times I_{LOAD})$$

where D = the duty cycle = $1 - (V_{IN} / V_{OUT})$, L is the inductor value, and I_{LOAD} is the maximum output current. Typically target crossover (f_C) for 1/6 of the RHPZ.

For example, if we assume $f_{OSC} = 500kHz$, $V_{IN} = 2.5V$, $V_{OUT} = 5V$, and $I_{OUT} = 0.5A$, then $R_{LOAD} = 10\Omega$. If we select $L = 4.7\mu H$, then:

$$f_{RHPZ} = 5 (2.5 / 5)^2 / (2\pi \times 4.7 \times 10^{-6} \times 0.5) = 84.7kHz$$

Choose $f_C = 14kHz$. Calculate C_C :

$$C_C = (V_{FB} / V_{OUT})(R_{LOAD} / R_{CS})(g_m / 2\pi \times f_C)(1 - D) = (0.8 / 5)(10 / 0.3) \times [135\mu S / (6.28 \times 14kHz)] (2.5/5) = 4.1nF$$

Choose 4.1nF.

Now select R_C so transient-droop requirements are met. As an example, if 4% transient droop is allowed, the input to the error amplifier moves $0.04 \times 0.8V$, or 32mV. The error-amp output drives $32mV \times 135\mu S$, or 4.32 μA , across R_C to provide transient gain. Since the current-sense transresistance is 0.3V/A, the value of R_C that allows the required load-step swing is as follows:

$$R_C = 0.3 I_{IND(PK)} / 4.32\mu A$$

In a step-up DC/DC converter, if L_{IDEAL} is used, output current relates to inductor current by:

$$I_{IND(PK)} = I_{OUT} / (1 - D) = I_{OUT} \times V_{OUT} / V_{IN}$$

So, for a 500mA output load step with $V_{IN} = 2.5V$ and $V_{OUT} = 5V$:

$$R_C = [(0.3 \times 0.5 \times 5) / 2.5] / 4.32\mu A = 69.4k\Omega$$

Note that the inductor does not limit the response in this case since it can ramp at $2.5V / 4.7\mu H$, or 530mA/ μs .

The output filter capacitor is then chosen so the C_{OUT} R_{LOAD} pole cancels the R_C C_C zero:

$$C_{OUT} \times R_{LOAD} = R_C \times C_C$$

For the example:

$$C_{OUT} = 69.4k\Omega \times 4.1nF / 10\Omega = 28\mu F$$

Choose 28 μ F for C_{OUT} . If the available C_{OUT} is substantially different from the calculated value, insert the available C_{OUT} value into the above equation and recalculate R_C . Higher substituted C_{OUT} values allow a higher R_C , which provides higher transient gain and consequently less transient droop.

If the output filter capacitor has significant ESR, a zero occurs at the following:

$$Z_{ESR} = 1 / (2\pi \times C_{OUT} \times R_{ESR})$$

If $Z_{ESR} > f_C$, it can be ignored, as is typically the case with ceramic output capacitors. If Z_{ESR} is less than f_C , it should be cancelled with a pole set by capacitor C_P connected from C_C to GND:

$$C_P = C_{OUT} \times R_{ESR} / R_C$$

If C_P is calculated to be <10pF, it can be omitted.

Step-Down Component Selection

This section describes component selection for the step-down converter, and for the main converter if used in step-down mode (SUSD = GND).

Step-Down Inductor

The external components required for the step-down are an inductor, input and output filter capacitors, and compensation RC network.

The SGM2100 step-down converter provides best efficiency with continuous inductor current. A reasonable inductor value (L_{IDEAL}) can be derived from the following:

$$L_{IDEAL} = [2(V_{IN}) \times D(1 - D)] / I_{OUT} \times f_{OSC}$$

This sets the peak-to-peak inductor current at 1/2 the DC inductor current. D is the duty cycle:

$$D = V_{OUT} / V_{IN}$$

Given L_{IDEAL} , the peak-to-peak inductor current is 0.5 I_{OUT} . The absolute-peak inductor current is 1.25 I_{OUT} . Inductance values smaller than L_{IDEAL} can be used to reduce inductor size; however, if much smaller values are used, inductor current rises, and a larger output capacitance may be required to suppress output ripple. Larger values than L_{IDEAL} can be used to obtain higher output current, but typically with larger inductor size.

Step-Down Compensation

The relevant characteristics for step-down compensation are as follows:

- Transconductance (from FB to C_C), g_{mEA} (135 μ S)
- Step-down slope-compensation pole, $P_{SLOPE} = V_{IN} / (\pi L)$
- Current-sense amplifier transresistance, R_{CS} (0.6V/A)
- Feedback-regulation voltage, V_{FB} (0.8V)
- Step-down output voltage, V_{SD} , in V
- Output-load equivalent resistance, R_{LOAD} , in $\Omega = V_{OUT} / I_{LOAD}$

The key steps for step-down compensation are as follows:

- 1) Set the compensation R_C to zero to cancel the $R_{LOAD} C_{OUT}$ pole.
- 2) Set the loop crossover below the lower of 1/5 the slope compensation pole or 1/5 the switching frequency.

If we assume $V_{IN} = 2.5V$, $V_{OUT} = 1.8V$, and $I_{OUT} = 350mA$, then $R_{LOAD} = 5.14\Omega$.

If we select $f_{OSC} = 500kHz$ and $L = 5.6\mu H$. $P_{SLOPE} = V_{IN} / (\pi L) = 142kHz$, so choose $f_C = 24kHz$ and calculate C_C :

$$C_C = (V_{FB} / V_{OUT})(R_{LOAD} / R_{CS})(g_m / 2\pi \times f_C) \\ = (0.8 / 1.8)(5.14 / 0.6) \times [135\mu S / (6.28 \times 24kHz)] \\ = 3.4nF$$

Choose 3.4nF.

Now select R_C so transient-droop requirements are met. As an example, if 4% transient droop is allowed, the input to the error amplifier moves 0.04 x 0.8V, or 32mV. The error-amp output drives 32mV x 135 μ S, or 4.32 μ A across R_C to provide transient gain. Since the current-sense transresistance is 0.6V/A, the value of R_C that allows the required load-step swing is as follows:

$$R_C = 0.6 I_{IND(PK)} / 4.32\mu A$$

In a step-down DC/DC converter, if L_{IDEAL} is used, output current relates to inductor current by the following:

$$I_{IND(PK)} = 1.25 I_{OUT}$$

So for a 250mA output load step with $V_{IN} = 2.5V$ and $V_{OUT} = 1.8V$:

$$R_C = (1.25 \times 0.6 \times 0.25) / 4.32\mu A = 43.4k\Omega$$

Choose 43.4k Ω .

Note that the inductor does somewhat limit the response in this case since it ramps at $(V_{IN} - V_{OUT}) / 5.6\mu\text{H}$, or $(2.5 - 1.8) / 5.6\mu\text{H} = 125\text{mA}/\mu\text{s}$.

The output filter capacitor is then chosen so the C_{OUT} R_{LOAD} pole cancels the R_C C_C zero:

$$C_{OUT} \times R_{LOAD} = R_C \times C_C$$

For the example:

$$C_{OUT} = 43.4\text{k}\Omega \times 3.4\text{nF} / 5.14\Omega = 29\mu\text{F}$$

Since ceramic capacitors are common in either 22 μF or 47 μF values, 22 μF is within a factor of two of the ideal value and still provides adequate phase margin for stability. If the output filter capacitor has significant ESR, a zero occurs at the following:

$$Z_{ESR} = 1 / (2\pi \times C_{OUT} \times R_{ESR})$$

If $Z_{ESR} > f_C$, it can be ignored, as is typically the case with ceramic output capacitors. If $Z_{ESR} < f_C$, it should be cancelled with a pole set by capacitor C_P connected from C_C to GND:

$$C_P = C_{OUT} \times R_{ESR} / R_C$$

If C_P is calculated to be <10pF, it can be omitted.

AUX Controller Component Selection External MOSFET

All SGM2100 AUX controllers drive external logic-level MOSFETs. Significant MOSFET selection parameters are as follows:

- On-resistance ($R_{DS(ON)}$)
- Maximum drain-to-source voltage ($V_{DS(MAX)}$)
- Total gate charge (Q_G)
- Reverse transfer capacitance (C_{RSS})

Use a MOSFET with on-resistance specified with gate drive at or below the main output voltage. The gate charge, Q_G , includes all capacitance associated with charging the gate and helps to predict MOSFET transition time between on and off states. MOSFET power dissipation is a combination of on-resistance and transition losses. The on-resistance loss is as follows:

$$P_{RDSON} = D \times I_L^2 \times R_{DS(ON)}$$

where D is the duty cycle, I_L is the average inductor current, and $R_{DS(ON)}$ is MOSFET on-resistance. The transition loss is approximately as follows:

$$P_{TRANS} = (V_{OUT} \times I_L \times f_{OSC} \times t_T) / 3$$

where V_{OUT} is the output voltage, I_L is the average inductor current, f_{OSC} is the switching frequency, and t_T is the transition time. The transition time is approximately Q_G / I_G , where Q_G is the total gate charge, and I_G is the gate-drive current (0.5A TYP).

The total power dissipation in the MOSFET is as follows:

$$P_{MOSFET} = P_{RDSON} + P_{TRANS}$$

Diode

For most AUX applications, a Schottky diode rectifies the output voltage. Schottky low forward voltage and fast recovery time provide the best performance in most applications. Silicon signal diodes (such as 1N4148) are sometimes adequate in low-current (<10mA), high-voltage (>10V) output circuits where the output voltage is large compared to the diode forward voltage.

AUX1 and AUX3 Compensation

The auxiliary controllers employ voltage-mode control to regulate their output voltage. Optimum compensation depends on whether the design uses continuous or discontinuous inductor current.

AUX1 and AUX3 Step-Up, Discontinuous Inductor Current

When the inductor current falls to zero on each switching cycle, it is described as discontinuous. The inductor is not utilized as efficiently as with continuous current, but in light-load applications this often has little negative impact since the coil losses may already be low compared to other losses. A benefit of discontinuous inductor current is more flexible loop compensation, and no maximum duty-cycle restriction on boost ratio.

To ensure discontinuous operation, the inductor must have a sufficiently low inductance to fully discharge on each cycle. This occurs when:

$$L < [V_{IN}^2 (V_{OUT} - V_{IN}) / V_{OUT}^3] [R_{LOAD} / (2f_{OSC})]$$

A discontinuous current boost has a single pole at the following:

$$f_P = (2V_{OUT} - V_{IN}) / (2\pi \times R_{LOAD} \times C_{OUT} \times (V_{OUT} - V_{IN}))$$

Choose the integrator cap so the unity-gain crossover, f_C , occurs at $f_{OSC} / 10$ or lower. Note that for many AUX circuits, such as those powering motors, LEDs, or other loads that do not require fast transient response, it is often acceptable to overcompensate by setting f_C at $f_{OSC} / 20$ or lower.

C_C is then determined by the following:

$$C_C = [2(V_{OUT} - V_{IN}) \times V_{IN} / ((2V_{OUT} - V_{IN}) \times V_{RAMP})] [V_{OUT} / (K(V_{OUT} - V_{IN}))]^{1/2} [(V_{FB} / V_{OUT})(g_M / (2\pi \times f_C))]$$

where:

$$K = 2L \times f_{OSC} / R_{LOAD}$$

and V_{RAMP} is the internal slope-compensation voltage ramp of 1.25V.

The $C_C R_C$ zero is then used to cancel the f_P pole, so:

$$R_C = R_{LOAD} \times C_{OUT} \times (V_{OUT} - V_{IN}) / [(2V_{OUT} - V_{IN}) \times C_C]$$

AUX1 and AUX3 Step-Up, Continuous Inductor Current

Continuous inductor current can sometimes improve boost efficiency by lowering the ratio between peak inductor current and output current. It does this at the expense of a larger inductance value that requires larger size for a given current rating. With continuous inductor current boost operation, there is a right-half-plane zero, Z_{RHP} , at the following:

$$Z_{RHP} = (1 - D)^2 \times R_{LOAD} / (2\pi \times L)$$

where $(1 - D) = V_{IN} / V_{OUT}$ (in a boost converter).

There is a complex pole pair at the following:

$$f_0 = V_{OUT} / [2\pi \times V_{IN} (L \times C_{OUT})^{1/2}]$$

If the zero due to the output capacitance and ESR is less than 1/10 the right-half-plane zero:

$$Z_{COUT} = 1 / (2\pi \times C_{OUT} \times R_{ESR}) < Z_{RHP} / 10$$

Then choose C_C so the crossover frequency f_C occurs at Z_{COUT} . The ESR zero provides a phase boost at crossover:

$$C_C = (V_{IN} / V_{RAMP}) (V_{FB} / V_{OUT}) [g_M / (2\pi \times Z_{COUT})]$$

Choose R_C to place the integrator zero, $1 / (2\pi \times R_C \times C_C)$, at f_0 to cancel one of the pole pairs:

$$R_C = V_{IN}(L \times C_{OUT})^{1/2} / (V_{OUT} \times C_C)$$

If Z_{COUT} is not less than $Z_{RHP} / 10$ (as is typical with ceramic output capacitors) and continuous conduction is required, then cross the loop over before Z_{RHP} and f_0 :

$$f_C < f_0 / 10, \text{ and } f_C < Z_{RHP} / 10$$

In that case:

$$C_C = (V_{IN} / V_{RAMP}) (V_{FB} / V_{OUT}) (g_M / (2\pi \times f_C))$$

Place:

$1 / (2\pi \times R_C \times C_C) = 1 / (2\pi \times R_{LOAD} \times C_{OUT})$, so that

$$R_C = R_{LOAD} \times C_{OUT} / C_C$$

Or, reduce the inductor value for discontinuous operation.

Compensation of AUX2 Inverter in Discontinuous Inductor Current

If the load current is very low ($\leq 40\text{mA}$), discontinuous current is preferred for simple loop compensation and freedom from duty-cycle restrictions on the inverter input-output ratio. To ensure discontinuous operation, the inductor must have a sufficiently low inductance to fully discharge on each cycle. This occurs when:

$$L < [V_{IN} / (|V_{OUT}| + V_{IN})]^2 R_{LOAD} / (2f_{OSC})$$

A discontinuous current inverter has a single pole at the following:

$$f_P = 2 / (2\pi \times R_{LOAD} \times C_{OUT})$$

Choose the integrator cap so the unity-gain crossover, f_C , occurs at $f_{OSC} / 10$ or lower. Note that for many AUX circuits that do not require fast transient response, it is often acceptable to overcompensate by setting f_C at $f_{OSC} / 20$ or lower.

C_C is then determined by the following:

$$C_C = [V_{IN} / (K^{1/2} \times V_{RAMP})] [V_{REF} / (V_{OUT} + V_{REF})] [g_M / (2\pi \times f_C)]$$

where $K = 2L \times f_{OSC} / R_{LOAD}$, and V_{RAMP} is the internal slope-compensation voltage ramp of 1.25V.

The $C_C R_C$ zero is then used to cancel the f_P pole, so:

$$R_C = (R_{LOAD} \times C_{OUT}) / (2C_C)$$

Compensation of AUX2 Inverter in Continuous Inductor Current

Continuous inductor current may be more suitable for larger load currents (50mA or more). It improves efficiency by lowering the ratio between peak inductor current and output current. It does this at the expense of a larger inductance value that requires larger size for a given current rating. With continuous inductor-current inverter operation, there is a right-half-plane zero, Z_{RHP} , at:

$$Z_{RHP} = [(1 - D)^2 / D] \times R_{LOAD} / (2\pi \times L)$$

where $D = |V_{OUT}| / (|V_{OUT}| + V_{IN})$ (in an inverter).

There is a complex pole pair at:

$$f_0 = (1 - D) / (2\pi(L \times C)^{1/2})$$

If the zero due to the output-capacitor capacitance and ESR is less than 1/10 the right-half-plane zero:

$$Z_{COUT} = 1 / (2\pi \times C_{OUT} \times R_{ESR}) < Z_{RHP} / 10$$

Then choose C_C such that the crossover frequency f_C occurs at Z_{COUT} . The ESR zero provides a phase boost at crossover:

$$C_C = (V_{IN} / V_{RAMP}) [V_{REF} / (V_{REF} + |V_{OUT}|)] [g_M / (2\pi \times f_C)]$$

Choose R_C to place the integrator zero, $1 / (2\pi \times R_C \times C_C)$, at f_0 to cancel one of the pole pairs:

$$R_C = (L \times C_{OUT})^{1/2} / [(1 - D) \times C_C]$$

If Z_{COUT} is not less than $Z_{RHP} / 10$ (as is typical with ceramic output capacitors) and continuous conduction is required, then cross the loop over before Z_{RHP} and f_0 :

$$f_C < f_0 / 10, \text{ and } f_C < Z_{RHP} / 10$$

In that case:

$$C_C = (V_{IN} / V_{RAMP}) [V_{REF} / (V_{REF} + |V_{OUT}|)] [g_M / (2\pi \times f_C)]$$

Place:

$$1 / (2\pi \times R_C \times C_C) = 1 / (2\pi \times R_{LOAD} \times C_{OUT}), \text{ so that}$$

$$R_C = R_{LOAD} \times C_{OUT} / C_C$$

Or, reduce the inductor value for discontinuous operation.

APPLICATION INFORMATION

Typical Operating Circuits

Figure 1, 2 and 3 show connections for AA and Li+ battery arrangements. Figures 7-13 show various connections for the AUX1, 2, 3 and 4 controllers. Figures 15, 16, and 17 show various connections for the SDOK, AUX10K, and SCF outputs.

Figure 1. Typical Operating Circuit for One Li+ Cell

In this connection, the main converter is operated as a step-down (SUSD = GND) and is powered from PVSU. This provides boost-buck operation for the main 3.3V output, so a regulated output is maintained over the Li+ 2.8V to 4.2V cell voltage range. The compound efficiency from the battery to the 3.3V output reaches 90%.

The step-down 1.8V (core) output is powered directly from V_{BATT} .

The CCD and LCD voltages are generated with a transformerless design. AUX1 generates +15V for CCD positive and LCD bias. AUX2 inverter generates -8V for negative CCD bias. The AUX3 controller generates a regulated current for a series network of four white LEDs that backlight the LCD.

Figure 2. Typical Operating Circuit for 2 AA Cells

Figure 2 is optimized for 2-cell AA inputs (1.5V to 3.4V) by connecting the step-down input (PVSD) to the main output (PVM). The main 3.3V output operates directly from the battery as a step-up (SUSD = PVSU). The 1.8V core output now operates as a boost-buck with efficiency up to 90%. The rest of the circuit is unchanged from Figure 1.

Figure 3. Typical Operating Circuit for 2 AA Cells and 1-Cell Li+

The SGM2100 can also allow either 1-cell Li+ or 2 AA cells to power the same design. If the step-down and main inputs are both connected to PVSU, then both the 3.3V and 1.8V outputs operate as buck-boost converters. There is an efficiency penalty compared to stepping down VSD directly from the battery, but that is not possible with a 1.5V input. Furthermore, the cascaded boost-buck efficiency compares favorably with other boost-buck techniques.

LED, LCD, and Other Boost Applications

Any AUX channel can be used for a wide variety of

step-up applications. These include generating 5V or some other voltage for motor or actuator drive, generating 15V or a similar voltage for LCD bias, or generating a step-up current source to efficiently drive a series array of white LEDs to display backlighting. Figure 7 and 8 show examples of these applications.

Multiple-Output Flyback Circuits

Some applications require multiple voltages from a single converter channel. This is often the case when generating voltages for CCD bias or LCD power. Figure 9 shows a two-output flyback configuration with an AUX channel. The controller drives an external MOSFET that switches the transformer primary. Two transformer secondaries generate the output voltages. Only one positive output voltage can be fed back, so the other voltages are set by the turns-ratio of the transformer secondaries. The load stability of the other secondary voltages depends on transformer leakage inductance and winding resistance. Voltage regulation is best when the load on the secondary that is not fed back is small compared to the load on the one that is fed back. Regulation also improves if the load-current range is limited. Consult the transformer manufacturer for the proper design for a given application.

Transformerless Inverter for Negative CCD Bias (AUX2)

AUX2 is set up to drive an external P-Channel MOSFET in an inverting configuration. DL2 drives low to turn on the MOSFET, and FB2 has inverted polarity and a 0V threshold. This is useful for generating negative CCD bias without a transformer, particularly with high pixel-count cameras that have a greater negative CCD load current. Figure 1 shows an example circuit.

Boost with Charge Pump for Positive and Negative Outputs

Another method of producing bipolar output voltages without a transformer is with an AUX controller and a charge-pump circuit, as shown in Figure 11. When MOSFET Q1 turns off, the voltage at its drain rises to supply current to V_{OUT+} . At the same time, C1 charges to the voltage V_{OUT+} through D1. When the MOSFET turns on, C1 discharges through D3, thereby charging C3 to V_{OUT} minus the drop across D3 to create roughly the same voltage as V_{OUT+} at V_{OUT-} , but with inverted polarity.

SGM2100

If different magnitudes are required for the positive and negative voltages, a linear regulator can be used at one of the outputs to achieve the desired voltages. One such connection is shown in Figure 12. This circuit is somewhat unique in that a positive-output linear regulator can regulate a negative voltage output. It does this by controlling the charge current flowing to the flying capacitor rather than directly regulating at the output.

SEPIC Boost-Buck

The SGM2100s' internal switch step-up, main, and step-down converters can be cascaded to make a high-efficiency boost-buck converter, but it is sometimes desirable to build a second boost-buck converter with an AUX_ controller.

One type of step-up/step-down converter is the SEPIC, shown in Figure 13. Inductors L1 and L2 can be separate inductors or can be wound on a single core and coupled like a transformer. Typically, a coupled inductor improves efficiency since some power is transferred through the coupling so less power passes through the coupling capacitor (C2). Likewise, C2 should have low ESR to improve efficiency. The ripple-current rating must be greater than the larger of the input and output currents. The MOSFET (Q1) drain-source voltage rating and the rectifier (D1) reverse-voltage rating must exceed the sum of the input and output voltages. Other types of step-up/step-down circuits are a flyback converter and a step-up converter followed by a linear regulator.

Applications for Status Outputs

The SGM2100 have four status outputs: $\overline{\text{SDOK}}$, $\overline{\text{AUX1OK}}$, $\overline{\text{AUX4OK}}$ and SCF. These monitor the output of the step-down channel, the AUX1 channel, and the status of the overload-short-circuit protection. Each output is open drain to allow the greatest flexibility. Figures 15, 16, and 17 show some possible connections for these outputs.

Using $\overline{\text{SDOK}}$, and $\overline{\text{AUX1OK}}$ for Power Sequencing

$\overline{\text{SDOK}}$ goes low when the step-down reaches regulation. Some microcontrollers with low-voltage cores require that the high-voltage (3.3V) I/O rail not be powered up until the core has a valid supply. The circuit in Figure 15 accomplishes this by driving the gate of a PFET connected between the 3.3V output and the processor I/O supply. Figure 16 shows a similar application where $\overline{\text{AUX1OK}}$ gates 5V power to the CCD only after the +15V output is in regulation. Alternately, power sequencing can also be implemented by connecting RC networks to delay the appropriate converter ON_ inputs.

Using SCF for Full-Load Startup

The SCF output goes low only after the step-up reaches regulation. It can be used to drive a P-Channel MOSFET switch that turns off the load of a selected supply in the event of an overload. Or, it can remove the load until the supply reaches regulation, effectively allowing fullload start-up. Figure 17 shows such a connection for the step-up output.

Designing a PC Board

Good PC board layout is important to achieve optimal performance from the SGM2100. Poor design can cause excessive conducted and/or radiated noise. Conductors carrying discontinuous currents and any high-current path should be made as short and wide as possible. A separate low-noise ground plane containing the reference and signal grounds should connect to the power-ground plane at only one point to minimize the effects of power-ground currents. Typically, the ground planes are best joined right at the IC.

Keep the voltage-feedback network very close to the IC, preferably within 0.2in (5mm) of the FB_ pin. Nodes with high dV/dt (switching nodes) should be kept as small as possible and should be routed away from high-impedance nodes such as FB_. Refer to the SGM2100 EV kit data sheet for a full PC board example.
